WILKINSON, J., 291.
WILLARD, DE FOREST, 64.
WILSON, J. C., 377.
WOODBURY, FRANK, 177, *Report*, 313, 426, 488, 532.

YOST, GEO. P., 196.
YOUNG, J. W., 337.

INDEX.

Abdomen, veratrum viride in wounds of the, 402.
Abdominal; affections, chronic pigmentation of the face in, 164; rings, stretched or torn, to relieve strangulated hernia, 337; typhus, treated by the douche, 384.
Abortion, double pneumonia and, 548.
Abscess: scrofulous, 109; mammary, prevention of, 189; psoas, 306; pelvic, 357; in the region of the rectum, 473.
Absorption of dialysed iron, 343.
Accidents of artificial anæsthesia, 147.
Acetate of lead in diarrhœa, 128.
Acid; *boracic*, in eczema, 413; *bromhydric*, in ulcer of the stomach, 325; *carbolic;* hypodermically, in piles, 34, 218; poisoning from, 144; a remedy against bee stings, 321; *chrysophanic*, in syphilis, 260; *muriatic;* in typhoid fever, 232; in hepatic colic, 387; *pyrogallic*, in epithelioma, 237; *salicylic;* as an anti-neuralgic, 144; in rheumatism, 211, 228, 262; in diabetes, 451; in infantile eczema, 482; in lupus, 481; *sulphurous;* as a disinfectant, 262; in cholera, 390; *thymic*, internal and external action of, 230.
Acids in treatment of rheumatism, 476.
Acne punctata, sulphur in, 128.
Aconite; in trigeminal neuralgia, 255; in pneumonia, 280.
Action; of thymic acid and thymate of soda, 230; of digitalis, 251; of ergot in relation to medical jurisprudence, 507; of duboisia and atropia, 547.
Active principle of eriodyction californicum, 392.
Acute; catarrh of the middle ear, management of, 100; opium poisoning, veratrum viride in, 401; poisoning, from ergot, 475.
Address of Prof. Donders at the opening of the International Medical Congress, 383.
Adenoid tumors in the naso-pharyngeal cavity, 386.
Administration of gelsemium, 17.
Advantages; of alcoholic surgical dressings, 122; of artificial anæsthesia, 147.
Advertisements, inset, the nuisance of, 505.
Affections; nervous, resulting from alcoholism, 88; chronic abdominal, pigmentation of the face in, 164; peritoneal, of drunkards, 392; mental, value of hyoscyamine in, 451; of the throat, chloral locally in, 456; spinal, method of applying fixed bandages in, 503.
Agaric in night sweats, 171.
Age; its relation to the seasonal death rate, 92, 113; to typhoid fever, 524; statistics of, 373; old, syphilis in, 476.
Agents; therapeutic, natural mineral waters as, 37; myotic and mydriatic, 385; medicinal, their influence on the fœtus, 436.
Aids to digestion, 435.
Air; sea and mountain, their hygienic effects, 40; mountain, in phthisis, 228; passages, veratrum viride in diseases of the, 400.
Alarming prognosis of protoplasm, 330.
Albuminuria; iodide and bromide of potassium in, 70; in healthy persons, 251.
Alcohol; poisoning by, 18; officinal, as a stimulant, 111; in fever, 250.
Alcoholic; surgical dressings, advantages of, 122; amblyopia, 295; dementia, contrasted with cerebral apoplexy with aphasia, 532.
Alcoholism, nervous affections resulting from, 88.
Alexis St. Martin, 44.
Alkalies and acids in treatment of rheumatism, 476.
Alkaloids; artificial, 216; of bark, 264; new, in ophthalmic surgery, 295; of squills as diuretics, 328.
Alligator oil, 524.
Aloes, powdered, as a dressing for wounds, 210.
Amaurosis; temporary, 232; narcotine, 469.
Amenorrhœa, 452.
America; inebriety and allied nervous diseases in, 228; leprosy in, 368.
American physicians, biographical dictionary of, 217.
Ammonia, carbonate of, in suffocating disorders, 495.
Ammoniacal sulphate of copper in tic douloureux, 194.
Ammonium, chloride of, combined with iron in heart disease, 319.
Amputation; after treatment of, 99; of the leg, 406.
Anæmia, inhalation of oxygen in, 150.
Anæsthesia; artificial, advantages and accidents of, 147; discovery of, 285; mesmeric, 326; fatal asphyxia occurring at remote periods after, 523.
Analysis of chlorine, 370.
Anaplastic operation, 361.
Anasarca treated by puncture in the lower extremities, 197.
Anatomy act of Ohio, 330.
Anchilostoma duodenale, 325.
Ancient; forms of nervous disease, 304; cosmetics, 418.
Aneurism; barium chloride in, 194; of the aorta, 449.
Anginous paralysis, treatment of, 303.
Animal; vaccination, 131, 505; and vegetable kingdoms, limits of the, 525.
Animals; lower, nausea in pregnancy in the, 237; relation of their diseases to public health, 499.
Another; treatment of sea sickness, 40; discoverer of the circulation of the blood, 327.
Anthelmintic, a new, 239.
Antidotes to poison, 414, 524.
Anti-; rheumatic ointment, 39; neuralgic, salicylic acid as an, 144; pyretic, external, iodoform as an, 165; febrile effects of cold enemata, 230; syphilitic, tayuya as an, 327; periodic, simaruba bean as an, 371; vaccination society, 395.
Antiseptic; treatment of wounds, 33, 67, 384; surgery, results of, 233; a cheap, 324; dressing in operations on the eye, 386; *vs.* simple treatment, 426.
Aorta, aneurism of the, 449.

Apex beat of the heart, 498.
Aphasia contrasted with alcoholic dementia, 533.
Aphonia in typhoid fever, 42.
Aphorisms on the nature and treatment of gonorrhœa, 32.
Apoplexy; veratrum viride in, 402; cerebral, with aphasia, contrasted with alcoholic dementia, 533.
Appearance; of the tongue in disease, 99, 201; microscopical, of fur from the tongue, 172.
Application of massage to the eyes and tonsils, 105.
Applications, for burns and scalds, 481.
Applying fixed bandages, method of, 503.
Appropriate treatment of hip joint disease, 489.
Arsenic; in asthma, 303; in cardiac disease, 328; in consumption, 456.
Arsenical wall paper, poisoning from, 78.
Arthritis, fungous, ignipuncture in the treatment of, 516.
Artificial; anæsthesia, advantages and accidents of, 147; alkaloids, 216; koumiss, 280; foods for infants, 358.
Ascites, capillary punctures in, 392.
Asparagin, 72.
Asphyxia; in childbirth, 471, 527; occurring at remote periods after anæsthesia, 523.
Asthma; dry, iodine in, 17; hysterical, 119; drug smoking in, 253; sulphate of morphia in, 284, 329, 330; arsenic in, 303.
Asylum organization, improvements suggested in, 195.
Atmospheric therapeutics, 265.
Atrophy of the optic nerves, 137.
Atropia; in tetanus, 167, 497; action of, 547.
Attacks, second, of yellow fever, 212.
Auditory range, methods of determining the, 386.
Audiphone, the, 550.
Aural therapeutics, 89.
Autopsy of Mr. Chas. Fechter, 152.
Axilla, dislocation of the humerus into the, 448.

Backbone needed on the prostitution question, 127.
Bad nutrition, inebriety from, 268.
Bag; of waters, the, as a dilator in labor, 283; spice, recipe for a, 346.
Bandage; solid india-rubber, 83; elastic tubular, in eczema and ulcers of the leg, 248; Esmarch's, modification of, 406; silicate, in treating fractured clavicle, 488.
Bandages, fixed, in spinal affections, method of applying, 503.
Bandaging the infant, 525.
Barium chloride in aneurism, 194.
Bark; the lower alkaloids of, 264; splints, 414; coto, in the diarrhœa of phthisis, 541.
Base of the skull, fracture of, 459.
Bath, cold, in enteric fever, 409.
Bathing, sea, rules for, 41.
Battey's operation, 15 cases of, 317.
Bean, simaruba, as an antiperiodic, 371.
Beat, apex, of the heart, 498.
Beef juice; ice cream and, 106; extracted by expression, 303.
Bee stings, carbolic acid a remedy for, 321.
Belladonna; in cholera infantum, 39; in strangulated femoral hernia, 240; in diseases of children, 312.
Benzoate of soda in diphtheria, 149.
Bilious fever of the South, 145.
Bills, the collection of, 103, 286.
Biographical dictionary of contemporary American physicians, 217.
Birth, evidences that dead infants were alive at, 327; plural, 553.
Bismuth; in cholera infantum, 390; in dysentery, 413; in ulcerated os, 436.
Bite of the skunk, 194.
Black tongue in children, 482, 484.
Bladder; inversion of the, 3; villous disease of the, 78; stone in the, 427.
Blindness; color, prevention of, 106; what form did Homer have? 107; the detection of, 295.
Blistering; the value of, 57; thimble, endermic use of morphia by, 106; finger, for neuralgia, 347.
Blood, another discoverer of the circulation of the, 327.
Board of health; national, its duties, 169; of Philadelphia, report of, 325.
Boatmen, sanitary regulation of, 81, 121.
Bodies; dead, method of preserving, 483; foreign, in the ear, position in removing them, 524.
Boiling temperature, organic resistance to a, 40.
Boldo, medical properties of, 14.
Boracic acid in eczema, 413.
Brain, severe injury of the, 529.
Bright's disease, 326, 384.
Bromhydric acid in ulcer of the stomach, 324.
Bromide of potassium in albuminuria, 70.
Brown-Séquard's theories of the nervous system, 391.
Brucine, physiological effects of, 326.
Bug, potato, cantharidine from the, 83.
Buildings, ventilation of, 38.
Burns and scalds, applications for, 481.

Cæcum, impacted, 287.
Calculi, intestinal, 392.
California; the medical law of, 394; health resort, 483.
Calomel; its value in the zymotic diseases of infancy, 474; in ophthalmology, 525.
Canal boatmen, sanitary supervision of, 81, 131.
Cantharides; prevention of cystitis after, 303; in gleet, 436.
Cantharidin from the potato bug, 83.
Cape Clear, measles at, 550.
Capillary puncture in ascites, 392.
Carbolic acid; in piles, 34, 219; poisoning by, 144; a remedy against bee stings, 321.
Carbonate of ammonia in suffocating disorders, 495.
Cardiac; dyspnœa, 149; disease, arsenic in, 328; its relation to gastric, 524; pulsations, fœtal, indications from the, 496.
Career for young men in veterinary medicine, 126.
Carotid triangle, removal of a fibro-cellular tumor from the, 68.
Carpenter, Dr., the sanitarian, 504.
Case; of sclerostoma duodenale, 40; of extra-uterine fœtation, 41; of congenital ventral gestation, 72; of substitution, 108; of congenital hydrocephalus, 130, 241; of atrophy of the optic nerves, 137; of strychnine poisoning, 196; of anasarca treated by punctures in the lower extremities, 197; of stricture of the male urethra, 199; of invagination of the large

intestine, 221; an anomalous, 225; of temporary amaurosis, 232; of dropsy, 371; of hepatic colic, attended with passage of gall stones, cured with muriatic acid, 387; of hydrophobia, 415; of stone in the bladder, 427; of fracture of the head of the humerus, 448; of amenorrhœa, 452; of twins in a primipara, 471; of strychnine poisoning, 525; of severe injury of the brain, 529; of laceration of cervix uteri, 553.
Cases; of ear disease, 5; of syphilis, 77; of puerperal convulsions, 200; of impacted cæcum and colon, 287; of Battey's operation, 317; of diabetes, 371; of narcotine amaurosis, 469; of cerebral apoplexy, with aphasia, contrasted with alcoholic dementia, 532.
Cataphasia, 216.
Cataract; operations, obviating the complications of, 294; Wolfe's operation for, 498.
Catarrh; of the middle ear, acute, management of, 100; chronic, sea-water gargle in, 324; post-nasal, wash in, 523.
Catarrhal; pneumonia, treatment of, 231; form of diphtheria, 298; affections of the upper air passages, yerba santa in, 377.
Catgut as a vehicle of infection, 255.
Causation; of sleep, 145; of cholera infantum, 177.
Cause; of flatulence, 331; of insanity, masturbation a, 542; of scurvy, 553.
Causes of cholera infantum, 282.
Caustics, 104.
Cautery, the solar, 282, 525.
Cavities of the heart, dilatation of the, 290.
Cavity, naso-pharyngeal, adenoid tumors in, 386.
Cerebral; hemorrhage, hemiplegia from, 380; apoplexy, with aphasia, contrasted with alcoholic dementia, 532.
Cerium oxalate in pertussis, 128.
Cervix uteri; rules for operating on epithelioma of the, 144; plugged for metrorrhagia, 195; laceration of the, 354, 405, 553.
Chancres; iodoform in, 166; do they necessarily precede syphilis? 171.
Changes in the U. S. Marine Hospital Service, 87, 351.
Charles A. Fechter, autopsy of, 152.
Cheap; doctors, necessity for, 276; antiseptic, 324.
Cheek, treatment of fistulæ and scars of the, 253.
Cheilo-angioscopy, 456.
Chemicals manufactured in the United States, 285.
Chicago, the Hahnemann Medical College of, 66.
Children; the night cough of, 61; enuresis in, 149; subcutaneous osteotomy in, 293; belladonna in diseases of, 312; treatment of dysentery in, 366; black tongue in, 482, 484; how to educate the color sense in, 518.
Chills, supposed congestive, caused by lumbrici, 393.
Chinese medicine, 43.
Chloasma lentigo, 82.
Chloral; non-tolerance of, by habit, 17; in vomiting in pregnancy, 297; locally, in throat affections, 456.
Chlorate of potash; in diphtheria, 39; in cystitis, 229; in epithelioma, 369.
Chloride; of barium in aneurism, 194; of lithium and platinum as nervines, 303; of ammonium combined with iron in heart disease, 319.
Chlorine, analysis of, 370.
Cholera; in the East, 88; in Japan, 373; sulphuric acid in, 390; *infantum*, belladonna in, 39; treatment of, 57, 121, 372; its causation 177, 282, 378; bismuth in, 390; *morbus*, hypodermic medication in, 117, 174.
Choleraic diarrhœa, hypodermic injections of morphia in, 410.
Chorea; the expectant plan in, 165; as a functional disorder, 251; hypodermic use of Fowler's solution in, 388; salicylate of sodium in, 413.
Chronic; contusion of the heel, 18; urticaria and eczema, 82, 143, 217; abdominal affections, pigmentation of the face in, 164; rheumatism, eucalyptus in, 237; indolent varicose ulcer, 246; catarrh, sea-water gargle in, 324; opium poisoning and valvular disease of the heart, veratrum viride in, 401; diseases of the stomach, electricity in, 553.
Chrysophanic acid in syphilis, 260.
Cinchona; the cultivation of, 264; cure for drunkenness, 347.
Cincinnati, letter from, 19.
Circulation of the blood, another discoverer of the, 327.
Circumscribed phlegmonous dermatitis, due to iodide of potassium, 516.
Cities, the mortality of, 264.
Civilization, nervous disease a correlative of, 80.
Clavicle; diagnosis of fractures of the, 32; fractured, treated by the silicate bandage, 488.
Climate, temperature a factor in, 192.
Clinical studies; of inebriety, 51, 134, 268; of gynæcology, 353.
Close of '79, 551.
Coffee; in typhoid fever, 39; taverns and temperance saloons, 214.
Cold; enemata, the anti-febrile effects of, 230, 373; bath in enteric fever, 409; douche in coma, 432.
Colic; infantile, 128; hepatic, muriatic acid in, 387.
Collapse, infantile, musk in, 149.
Collection; of bills, 103; of medicinal plants, 482.
College; Hahnemann, of Chicago, 66; items, 330; Jefferson Medical, presentation of portrait of Prof. Meigs to, 549.
Colleges; new medical, 130; sex and color, 153.
Colles' fracture, 294.
Colon; impacted, 287; stricture of, 334.
Color; blindness, prevention of, 106; colleges, 153; detection of, 295; of the eyes, myopia and the, 404; sense in children, how to educate it, 518.
Coma, the cold douche in, 432.
Combination; of iron and chloride of ammonium in heart disease, 319; in whooping cough, 346.
Combined external and internal version, 84.
Comments on quinine legislation, 219.
Commercial impositions on the profession, 346.
Communications, confidential, to physicians, 502.
Complete; recovery from fracture of the skull, 71; rupture of the perineum, 357.
Complicated fracture, 364.
Complication of intermittents, intestinal worms as a, 86.
Complications of cataract operations obviated, 294.
Compound comminuted fracture of the elbow-joint, 448.
Conception; results of the prevention of, 40; in prostitutes, 261.

Condensed milk as infant food, 523.
Condition, sanitary, of Havana, 131.
Conditions, telluric and meteorological, in relation to malarial diseases, 402.
Conduction of the spinal cord, paths of, 437.
Confidential communications to physicians, 502.
Congenital; ventral gestation, 72; hydrocephalus, 130, 241, 306.
Congestive chills, supposed, caused by lumbrici, 393.
Conjunctivitis, purulent, of the newborn, 171.
Consanguineous marriages, results of, 83, 152.

Hydrophobia; curare in, 261; in rabbits, 391; case of, 415.
Hygienic effects of sea and mountain air, 40.
Hyoscyamine; its value in mental affections, 451; in epileptic excitement, 496.
Hypertrophic elongation of the supra-vaginal portion of the neck of the womb, 463.
Hypertrophy; of the heart, 290; tonsillar, succus limonis in, 346; removal of part of tonsils for, 488.
Hypodermic; use; of carbolic acid in piles, 34; quinine for, 260; medication in cholera morbus, 117; injections in cholera, 174; of morphia, 263, 349; in asthma, 284; in choleraic diarrhœa, 410; use of kinate of quinia, 369; of Fowler's solution in chorea, 388; of morphia, 423, 431; syringe, how to select a, 501.
Hypophosphites, their value in phthisis, 387.
Hyposulphites in smallpox, 189.
Hysterical; convulsions, 118; paraplegia, 118; asthma, 119; tetanus, 437.
Hystero-chorea, 485; epilepsy, 519.
Ice cream; and beef juice, 106; in the treatment of mammary inflammation, 151; medicated, 294.
Ideal of a healthy people, 441.
Ignipuncture in the treatment of fungous arthritis, 516.
Ignorance of veterinary medicine, 217.
Illinois, malarial diseases in, 106.
Immediate as distinguished from the permanent treatment of disease, 457.
Impacted cæcum and colon, 287.
Importance of treating the paroxysm of neuralgia, 173.
Impositions, commercial, on the profession, 326.
Impotence, from spermatorrhœa, 297.
Impure; eucalyptus oil, 83; milk, its relation to infant mortality, 502.
Imputations, improper, 153.
Inactivity in the treatment of disease, 1.
Inanition, nutrition and, 389.
Incipient hip joint disease, 488.
Increase of consumption in southern latitudes, 302.
Incontinence; of urine, 33; pyloric, 106.
Index, the scapular, in man, 153.
India-rubber bandage, solid, 83.
Indian corn, the poison of, 217.
Indications from the fœtal cardiac pulsations, 496.
Indolent varicose ulcer, chronic, 246.
Induction of premature labor in puerperal eclampsia, 190.
Inebriates, legislation for, 500.
Inebriety; clinical studies of, 51, 134, 268; and allied nervous diseases in America, 228.
Infancy, value of calomel in the zymotic diseases of, 474.
Infant; mortality, relation of impure milk to, 502; food, condensed milk as, 523; bandaging the, 525.
Infantile; colic, 128; collapse, musk in, 149; intertrigo, 149; ophthalmia, prevention of, 172; eczema, salicylic acid in, 452; convulsions, 483.
Infants; ulcerations in, 61; dead, evidences that they were born alive, 327; artificial foods for, 358; intertrigo of, 436; obscure convulsive disorder in, 503; asphyxia of, 527.
Infection, catgut as a vehicle of, 255.
Inferior maxilla, myeloid sarcoma of the, 488.
Inflamed joints, treatment of, 34.
Inflammation; mammary, treated by ice, 151; of the eyes, 369.
Influence; of singing upon health, 30; of medicinal agents on the fœtus, 436.
Influences, planetary, 352.
Ingrown toe nail, treatment of, 105.
Inhalation; of eucalyptus oil, 145; of oxygen in anæmia, 150.
Injection; subcutaneous, of ergot in neuralgia, 150; hypodermic, in cholera, 174; of morphia, 263, 284; intravenous, of milk, 294; intra-tympanic, 296; intra-uterine, of hot water in post-partum hemorrhage, 316.
Injuries; self-inflicted, 118; toleration of the peritoneum to resist, 512.
Injured eyes, dressings for, 296.
Injury of the brain, 529.
Insane; the sedative treatment in the excitement of the, 320; responsibility of the, 328; progress in treatment of the, 417.

Insanity, contagious, 13; masturbation a cause of, 542.
Inset advertisements, the nuisance of, 505.
International; quarantine, 263; medical congress, Dr. Sayre at the, 394.
Instantaneous urticaria, 238.
Instrument of resuscitation, 105.
Instruments; surgical, tests and preservation of, 101; of precision, recent, 236; Staufer's uterine, 505.
Insufficient food, diseases from, 366.
Intemperance, its relation to violent deaths, 502.
Intermittent hemorrhages caused by malaria, 413.
Internal; and external version, 84; parasites, the effects of, 151; action of thymic acid and thymate of soda, 230; use of tar, 532.
International medical congress, 328.
Intertrigo of infants, 436.
Intestine, large, invagination of the, 221.
Intestinal; worms as a complication of intermittents, 86, 152; occlusion and obstruction, diagnosis and treatment of, 164, 408; calculi, 392.
Intra-; venous injection of milk, 294; tympanic injections, 296; uterine medication, 315.
Introducing the hand into the rectum, 211.
Inunction in scarlet fever, 162, 163.
Invalids, a home for, 484.
Inversion; of the bladder, 3; partial, of the puerperal uterus, 195.
Inverted toe nail, 64.
In vino veritas, 129.
Iodide; of potassium; in albuminuria, 70; circumscribed phlegmonous dermatitis, due to, 516; in ophthalmology, 525; of ethyl in œdematous laryngitis, 303.
Iodine; in coryza, 14; in dry asthma, 17; in malarial fever, 189; to the os uteri in vomiting of pregnancy, 277.
Iodoform; as an external antipyretic, 165; in chancres, 166; ointment in gonorrhœal orchitis, 171; lozenges, 194; in fissured nipples, 436; and quinia in ulcers, 545; use of, 553.
Ipecac. in dysentery, 107, 474.
Irido-choroiditis, sympathetic, 386.
Iron; persulphate of, in hæmoptysis, 219; and chloride of ammonium combined in heart disease, 319; dialysed, absorption of, 343.
Irritable ulcer of the rectum treated by forcible dilatation, 62.
Itching, to relieve, 501.

Jaborandi; in obstinate hiccough, 41; in puerperal convulsions, 165.
Japan; syphilis in, 352; cholera in, 373.
Japanese surgeons, native, 242.
Joint; diseases, diagnosis and treatment of, 293; elbow, fracture of the, 448; hip, incipient disease of the, 489; resection of the, 497.
Joints, inflamed, treatment of, 34.
Jurisprudence, medical, relation of the action of ergot to, 507.

Kidneys, surgical operations on the, 102.
Kinate of quinine hypodermically, 369.
Kingdoms, animal and vegetable, limits of the, 525.
Kiss, disease from a, 254.
Koumiss, artificial, 280.
Labor; rules for managing the third stage of, 33; premature, in puerperal eclampsia, when to induce it, 190; the bag of waters as a dilator in, 283.
Laceretion of the cervix uteri, 353, 405, 553.
Lactation by males, 414.
Large; doses of chlorate of potash in diphtheria, 39; ovarian tumors, diagnosis of, 61; uterine fibroid, 202; intestine, invagination of the, 221.
Laryngeal phthisis, 250.
Laryngitis, œdematous, iodine of ethyl in, 303.
Lateral lithotomy, 427.
Latitudes, southern, increase of consumption in, 302.
Lavements, vaginal, for vomiting of pregnancy, 217.
Law, medical, of California, 394.
Laws, fixed, why not recognized by scientific medicine, 544.
Lead, acetate of, in diarrhœa, 128.
Left carotid triangle, removal of a fibro-cellular tumor from the, 68.
Leg; ulcers of the, treated by an elastic tubular bandage, 247; amputation of the, 406.
Legal objections to cremation, 129.
Legislation; emotional 281; for the public health, 437, 460; for inebriates, 500.
Leprosy in America, its dangers and prevention, 368.
Letter; from London, 18, 62, 129; from Cincinnati, 19.
Life; of the fœtus in utero after the mother's death, 166; dangers of improved habits of, 304; school, defects of vision produced by, 343; policies, relation of diseases of the ear, to, 386.
Limits of the animal and vegetable kingdoms, 525.
Lining membrane of the uterus, fungoid degeneration of the 354.
Lip, sebaceous tumor of the, 427.
List; of changes in Marine Hospital Service, 87, 351; visiting, physicians', 502.
Lister's method in country practice, 41.
Lithium, chloride of, as a nervine, 303.
Lithotomy; lateral, 417; for stone in a female, 482.
Lithotrity, the principles and practice of, 257.
Local; treatment of phimosis, 42, use of chloral in throat affections, 456.
London, letter from, 18, 62, 129.
Long standing neuralgia cured by aconitia, 255.
Lower; extremities, punctures in the, for anasarca, 197; animals, nausea in pregnancy in the, 237; alkaloids of bark, 264; third of the radius, giant-celled sarcoma of the, 313.
Lozenges, iodoform 194.
Lumbrici; supposed congestive pills, produced by, 393.
Lunatic asylum organization, improvements suggested in, 195.
Lupus, salicylic acid in, 481.

Mackinnon pen, 220.
Maize stigmas in urinary disease, 481.
Maladies, nervous, of uncultivated people, 390.
Malaria; what is it? 254; prevalence of, 308; intermittent hemorrhages caused by, 413; a prophylactic in, 481.
Malarial; diseases in Illinois, 106; fever, 174;

iodine in, 189; periodicity of, 261; poisoning, 350; peculiar sequelæ of, 547; relation of telluric and meteorological conditions to, 402.
Male urethra, stricture of the, 199.
Males, lactation by, 414.
Mammary; inflammation treated by ice, 151; abscess, prevention of, 189; gland, fibroma of the, 426.
Man the scapular index in, 153.
Management; of acute catarrh of the middle ear, 100; of diphtheria, 297; of opium and morphia poisoning, 325.
Managing the third stage of labor, rules for, 33.
Manipulation in reduction of dislocation, 459.
Manufacture of chemicals in the United States, 285.
Marriages, consanguineous, results of, 83, 152.
Marrying near relations, 550.
Massage applied to the eyes and tonsils, 105.
Mastitis, phytolacca decandra in, 408.
Masturbation as a cause of insanity, 542.
Material for splints, 347.
Masterly inactivity in the treatment of disease, 1.
Matters, medical, the Talmud on, 418.
Maxilla, inferior, myeloid sarcoma of the, 490.
Measles, the cooling treatment in, 304; at Cape Clear, 550.
Mechanical remedies in hay fever, 545.
Medical; properties of boldo, 14; colleges, new, 130; department of the U. S. Army, organization of the, 175; missionaries, 264; congress, international, 328; Dr. Sayre at the, 394; law of California, 394; education, higher, 395; matters, the Talmud on, 418; jurisprudence, relation of the action of ergot to, 507; use of iodoform, 553.
Medical Societies—
American Dental Association—Annual meeting, 153.
American Dermatological Association—Annual meeting, 247.
American Ophthalmological Society—Annual meeting, 110.

Official list of changes in the U. S. Marine Hospital service, 87, 351.
Officinal alcohol as a stimulant, 111.
Ohio anatomy act, 330.
Oil; eucalyptus, impure, 83; inhalation of, 145; of gynocardia in skin disease, 260; of sassafras in rhus poisoning, 260; alligator, 524.
Ointment; anti-rheumatic, 39; iodoform, in gonorrhœal orchitis, 171.
Old age, syphilis in, 476.
Olecranon process, spindle-celled sarcoma over the, 313.
Operation; for stricture of the male urethra, 199; for stone, sterility as a result of the, 211; Battey's, 317; for varicocele, 343; anaplastic, 361; for laceration of the cervix uteri, 405; for stone, in a female, 482; for cataract, Wolfe's, 498.
Operations; surgical, on the kidneys, 102; on epithelioma of the cervix uteri, rules for, 144; for cataract, obviating the complications of, 294; in the subjects of constitutional disease, 384; on the eye, antiseptic dressings in, 386.
Ophthalmia; infantile, the prevention of, 172; neonatorum, treatment of, 408.

Ophthalmic; surgery, alkaloids in, 205; practice, pilocarpin in, 391.
Ophthalmology, iodide of potassium and calomel in, 525.
Opium poisoning; the management of, 325; veratrum viride in, 401.
Optic nerves, atrophy of the, 137.
Orchitis, gonorrhœal, iodoform ointment in, 171.
Organic resistance to a boiling temperature, 40.
Organization; of U. S. army medical department, 175; of lunatic asylums, suggested improvements in, 195.
Osteotomy, subcutaneous, in children, 293.
Os; uteri; rigid; tartar emetic in, 31, 109; frequency of, 196; iodine to the, in vomiting of pregnancy, 277; internum, stenosis of the, 202; ulcerated, bismuth in, 436.
Otitis media, 155.
Ovarian; tumors, diagnosis of, 61; epilepsy, 206; pressure in hystero-epilepsy, 519.
Ovariotomy, 139.
Oxalate of cerium in pertussis, 128.
Oxygen, inhalation of, in anæmia, 150.
Ozæna, recent suggestion for, 545.

Palm of the hand, psoriasis of the, 143.
Pancreatic digestion, 45.
Paper, arsenical poisoning from, 78.
Paralysis; from spermatorrhœa, 297; anginous, treatment of, 303; general symptoms and diagnosis of, 341.
Paraplegia, hysterical, 118.
Parasite, a troublesome, 4.
Parasites, internal, effects of, 151.
Paroxysm of neuralgia, importance of treating the, 173.
Part of tonsils removed, for hypertrophy, 488.
Partial inversion of the puerperal uterus, 195.
Passage of gall stones, 387.
Passages, air, veratrum viride in diseases of the, 400.
Pathological museums of Great Britain, 397.
Pathology of inebriety, 268.
Paths of conduction of the spinal cord, 437.
Patients, the perignosis of, 252.
Peculiar; micrococcus in gonorrhœal discharge, 194; sequelæ of malarial poisoning, 548.
Pelvic abscess, 353.
Pen, the Mackinnon, 220.
People; uncultivated, nervous maladies of, 390; healthy, the ideal of a, 441.
Percentages from druggists, 392.
Perchloride of iron, tincture of, in diphtheria, 303.
Perignosis of patients, 252.
Perineum, ruptured, 353.
Peritoneum, its toleration to resist injuries, 512.
Periodic dipsomania, 101.
Periodicity of malarial disease, 261.
Peritoneal affections of drunkards, 392.
Permanent, as distinguished from the immediate treatment of disease, 457.
Persulphate of iron in hæmoptysis, 219.
Pertussis; naphthalin in, 196; cerium oxalate in, 128.
Petechial typhus treated by the douche, 384.
Petroleum ointment in eczema, 194.
Pharmaceutical use of gelatine, 474.
Pharmaceuticals, new, 43, 131.
Pharmacy and medicine, the relations of, 412.
Pharyngitis, ergot in, 128.
Philadelphia; water supply, 87; board of health, report of the, 325.
Phimosis, local treatment of, 42.
Phlegmonous dermatitis due to iodide of potassium, 516.
Phosphornecrosis, 450.
Phthisis; mountain air in, 228; night sweats in, 237; laryngeal, 250; the hypophosphites in, 387; coto bark in the diarrhœa of, 541.
Physicians; in foreign countries, 131; contemporary American, 217; as sellers of drugs, 218, 305; confidential communications to, 502; pocket record and visiting list, 502.
Physiological; effects of brucine and strychnine, 326; experiments with ergot, 365.
Physiology, experimental, 45.
Physostigmine, crystallized salicylate of, 552.
Phytolacca decandra in mastitis, 408.
Picrotoxin in night sweats, 501.
Pigmentation of the face in chronic abdominal affections, 164.
Piles; hypodermic use of carbolic acid in, 34; external, for, 501.
Pill; for constipation, 39.
Pilocarpin; in obstetrics, danger of, 229; effect of, on the uterus, 385; in ophthalmic practice, 391; dangers from the use of, 436.
Pin, safety, swallowing a, 525.
Plan, expectant, in chorea, 165.
Planetary influences, 352.
Plants, medicinal, the collection of, 482.
Platinum, chloride of, as a nervine, 303.
Plugging; the cervix uteri for metrorrhagia, 195; the posterior nares, 416.
Plural births, 553.
Pneumonia; herpes labialis in, 151; catarrhal, treatment of, 231; aconite in, 280; croupous, treatment of, 319, 366; double, 548.
Pocket record, physicians', 502.
Podophyllin, how to give it, 107.
Poison; yellow fever, nature of the, 148; of Indian corn, 217; of the toad, 260; of typhoid fever, 261; scarlatinal, forms of, 413.
Poisons, antidotes to, 414, 524.
Poisoning; by alcohol, 18; by veratrum viride, 63, 167; from arsenical wall paper, 78; by carbolic acid, 144; by strychnine, 196, 525; by rhus, sassafras oil in, 260; by opium and morphia, 325; veratrum viride in, 401; malarial; singular form of, 350; peculiar sequelæ of, 548; by ergot, 475.
Poisonous mushrooms, 32, 238, 243.
Policies, life, diseases of the ear related to, 386.
Politico-economical reflections on the profession of medicine, 60.
Popular notions on stuttering, 107.
Poroplastic splints, 294.
Position in removing foreign bodies from the ear, 524.
Possible explanations of miraculous cures, 301.
Posterior; nares, new method of plugging the, 416; paretial engagement of fœtal head, 495.
Post-mortem, on stricture of colon, 334.
Post-nasal catarrh, wash in, 523.
Post-partum hemorrhage; treated by intra-uterine injection of hot water, 316; in a primipara, 471.
Postponing the use of spectacles, 316.
Potash, chlorate of, in diphtheria, 39.

Potassium; iodide and bromide of, in albuminuria, 70; circumscribed phlegmonous dermatitis due to, 516; in ophthalmology, 525; chlorate of, in cystitis, 237; in epithelioma, 369.
Potato bug, cantharidin from the, 83.
Powder; cosmetic, 104; Dover's, 149.
Powdered aloes as a dressing for wounds, 210.
Powers, therapeutical, of fuchsine, 280.
Practice; country, Lister's method in, 41; of lithotrity, 257; ophthalmic, pilocarpin in, 391; notes from, 460.
Practitioners, German physicians as, 285.
Precision, some recent instruments of, 236.
Pregnancy; the vomiting of, galvanism in, 18; vaginal lavements for, 217; iodine to the os uteri for, 277; chloral in, 297; treatment of, 317, 511; at eight years of age, 220; molar, 225; in the lower animals, nausea in, 237.
Premature labor in puerperal eclampsia, 190.
Prescription for spermatorrhœa, 369.
Preservation of surgical instruments, 101.
Preserving dead bodies, 483.
Pressure; in wounds, 432; ovarian, in hystero-epilepsy, 519.
Prevalence; of nervous disease, 304; of malaria, 308.
Prevention; of relapses in typhoid fever, 13; of conception, results of, 40; of color blindness, 106; of infantile ophthalmia, 172; of mammary abscess, 189; of cystitis after cantharides, 303; of leprosy in America, 368.
Primipara, twins in a, 471.
Principle, active, of eriodyction californicum, 392.
Prize essays, 130.
Process, olecranon, spindle-celled sarcoma over the, 313.
Procidentia uteri, 353.
Production; synthetic, of salicin, 391; of sex, theories of, 419.
Profession; of medicine, politico-economical reflections on the, 60; how some "dirty shillings" are made by the, 170; commercial impositions on the, 326.
Prognosis; in fractures of the skull, 18; in smallpox, 239; alarming, of protoplasm, 330.
Progress; of dermatology in the United States, 247; of metalloscopy, 307; of the metric system, 323; in treatment of the insane, 417.
Prolapsus ani, ergotine in, 369, 433.
Properties, of boldo, 14.
Prophylactic; in scarlet fever, inunction as a, 162; in scarlatina, 346; treatment of puerperal fever, 385; in malaria, 481.
Prophylaxis of scarlatina and diphtheria, 484.
Prostitutes, frequency of conception in, 261.
Prostitution question, need of more backbone on the, 127.
Protection, constitutional, of state medicine, 279.
Prurigo podicis, 104.
Pruritus vulvæ, 171.
Psoas abscess, 306.
Psoriasis; treatment of, 61, 83, 143; varieties of, 325.
Public; and private buildings, ventilation of, 38; health legislation, 437, 460; health, relation of diseases of animals raised for food to, 499.
Puerperal; metritis, 23; convulsions, jaborandi in, 165; two cases of, 200; treatment of, 329; eclampsia, when to induce premature labor in, 190; uterus, partial inversion of the, 195; fever, prophylactic treatment of, 385; diseases, veratrum viride in, 402.
Pulsations, fœtal cardiac, indications from the, 496.
Punch, a sip of, 395.
Puncture; in lower extremities for anasarca, 197; in stricture of the urethra, 199; capillary, in ascites, 372; for intestinal obstruction, 408.
Punishment, corporal, 173.
Purgative, euonymin as a, 171.
Purgatives in the early stages of typhoid, 452.
Purulent conjunctivitis, of the newborn, 171.
Puzzle, a sanitary, 129.
Pyloric incontinence, 106.
Pyrogallic acid in epithelioma, 237.

Quack; 16; medicine, the varieties of, 345.
Question; of tying the cord, 58; of prostitution, need of more backbone on the, 127; the woman, Dr. Yandell on, 132; of bills, 286.
Quarantine, international, 263.
Quinine; on the free list, 43, 61, 110, 154, 219; sulphate of, Warner's sugar-coated pill, 43; in gout, 128; speculators, a victim of the, 185; kinate of, hypodermically, 369; in delirium tremens, 370; and iodoform in ulcers, 545.

Rabbits, hydrophobia in, 391.
Radical cure of hernia, 238, 385.
Radius; diagnosis of fracture of the, 32; giant-celled sarcoma of the, 313.
Range, auditory, methods of determining the, 386.
Real and hysterical tetanus, 437.
Reasons in favor of physicians dispensing drugs, 305.
Recent; instruments of precision, 236; suggestion for ozæna, 545.
Reception to Surgeon General Wales, 505.
Recipe for a spice bag, 346.
Record, physician's pocket, 502.
Recovery; from fracture of the skull, 71; from mental disease, 72; from atropia of the optic nerves, 137; from invagination of the large intestine, 221.
Rectal diseases, diagnosis of, 42.
Rectocele, 357.
Rectum; irritable ulcer of the, treated by forcible dilatation, 62; a simple cure for, 109; introducing the hand into the, 211; abscess in the region of the, 473.
Reduction of dislocation, 459.
Reflections, politico-economical, on the profession of medicine, 60.
Refurbished rusty weapons, 481.
Regulation, sanitary, of sailors and boatmen, 81.
Relapses in typhoid fever, 13, 375.
Relation; of age and the seasonal death rate, 92, 113; of religious belief to epidemics, 198; of memory, 281; of diseases of the ear to life policies, 386; of telluric and meteorological conditions to malarial diseases, 402; of pharmacy and medicine, 412; of the diseases of animals raised for food to the public health, 499; of impure milk to infant mortality, 502; of intemperance and temperance to violent

deaths, 502; of the action of ergot to medical jurisprudence, 507; of age to typhoid fever, 524; of cardiac and gastric disease, 524.
Relations, near, marriage of, 550.
Relief; of strangulated hernia by tearing or stretching the abdominal rings, 337; of itching, 501.
Remedies; in tetanus, 128; new, the study of, 521; mechanical, in hay fever, 545.
Remedy; against bee stings, carbolic acid a, 321; for tapeworm, 546.
Remit money without risk, 546.
Remittents, sudorific in, 390.
Removal; of wens, 4; of a fibro-cellular tumor from the left carotid triangle, 68; of depression in fracture of the skull, 71; of moles, 194; of the smell of musk, 436; of part of the tonsils, for hypertrophy, 488; of foreign bodies from the ear, 524.
Report; of the autopsy of Mr. Chas. A. Fechter, 152; of a case of stricture of the male urethra, 199; of the Philadelphia Board of Health, 325; of the surgeon general, 522.
Resection of the elbow joint, 497.
Resistance; organic, to a boiling temperature, 40; of injuries by the peritoneum, 512.
Resort, health, California, 483.
Responsibility of the insane, 328.
Rest; inebriety from want of 270; in wounds, 432.
Resuscitation, instrument of, 105.
Results; of the prevention of conception, 40; of consanguineous marriages, 83; of treatment in Vienna, 175; of puncture in stricture of the male urethra, 199; of the operation for stone, 211; of antiseptic surgery, 233.
Retina, displaced, retained by the wire seton, 76.
Revelations in sanitary science, 215.

Taverns, coffee, 214.
Tayuya as an anti-syphilitic, 327.
Tea, its effects on the system, 518.
Tearing or stretching the abdominal rings, in strangulated hernia, 337.
Teeth, vitality of the, 348.
Telluric conditions, in relation to malaria, 402.
Temperance saloons, 214.
Temperature; boiling, organic resistance to a, 40; a factor in climate, 192.
Temporary amaurosis, 232.
Testimony, unprofessional, 285.
Tests of surgical instruments, 101.
Tetanus; remedies in, 128, 167; real and hysterical, 437; treated with atropine, 497.
Theories; Brown-Séquard's, of the nervouss ystem, 391; of sex production, 419.
Theory; the germ, 61, 69; of sea sickness, 365.
Therapeutic; agents, natural mineral waters as, 37; value of drug smoking in asthma, 253; powers of fuchsine, 280; value of the melia azedarach, 282; value of yerba santa, 377; use of duboisia in eye diseases, 464.
Therapeutics; aural, 89; atmospheric, 265; various methods in, 455.
Thermo-cautery and thermantidote, the, 275.
Thimble blistering, endermic use of morphia by, 106.
Things that are sad, 527.
Third stage of labor, managing the, 33.
Three cases of diabetes, 371.
Throat; the, in tuberculosis, 407; affections, chloral locally in, 456.
Thymic acid and thymate of soda, internal and external action of, 230.
Tic douloureux, ammoniacal sulphate of copper in, 194.
Tinea tonsurans, treatment of, 517.
Tincture ferri perchloridi in diphtheria, 303.
Tinnitus aurium, 296.
Toad, the poison of the, 260.
Toadstool poisoning, 243.
Tobacco amblyopia, 295.
Toe nail, inverted, 64, 105.
Toleration of the peritoneum to resist injuries, 512.
Tongue; its appearance in disease, 99, 201; microscopical appearance of fur from the, 172; in typhoid fever, 219; black, in children, 482, 484.
Tonsillar hypertrophy, succus limonis in, 346.
Tonsils; massage applied to the, 105; partly removed, for hypertrophy, 488.
Tracheotomy in croup, 250.
Trade, the quinine, 154.
Training school for nurses, 417.
Trance, hysterical, 118.
Traumatic; ruptures of the heart, 167; tetanus, successfully treated with atropine, 497.
Treatment; of disease, 1, 457; of gonorrhœa, 32; of wounds by antiseptics, 34, 67; of inflamed joints, 34; of sea sickness, 40; of phimosis, 42; of dyspepsia, 56; of cholera infantum, 57, 121; of psoriasis, 61; of irritable ulcer of the rectum by forcible dilatation, 62; of displaced retina by the wire seton, 76; after amputation, 99; of ingrown toe nail,

105; of nocturnal seminal emissions, 121; of syphilis, 143, 231, 409; of eczema, 143, 252; of mammary inflammation by ice, 151; of intestinal occlusion, 164; of vaginismus, 166; of the paroxysm in neuralgia, 173; results of, in Vienna, 175; of anasarca, 197; of chronic urticaria, 217; of catarrhal pneumonia, 231; of strangulated femoral hernia, 240; of ulcers of the leg, 248; of the hemorrhagic diathesis, 251; of fistulæ and scars of the cheek, 253; of excitement, 275; of venereal warts, 276; of dilatation of the heart with digitalis, 290; of joint diseases, 293; of diphtheria and anginous paralysis, 303; cooling, in measles, 304; of spinal diseases, 309; of post-partum hemorrhage, 316; of fibroid uterine tumors, 315; of croupous pneumonia, 319; in the excitement of the insane, 320; of diphtheria, 321, 343, 456, 552; of flatulence, a symptom of dyspepsia, 331; of fracture of the femur, 338; of cough, 342; of strangulated hernia, 361; of dysentery in children, 366; of pneumonia, 366; of catarrhal affections, 377; of abdominal and petechial typhus, 384; of uterine fibromas, 385; of puerperal fever, 385; of ophthalmia neonatorum, 408; of the insane, 417; antiseptic *vs.* simple, 426; of prolapsus ani, 433; of diabetes, 451; of dropsy, 459; of rheumatism by alkalies and acids, 476; of fractured clavicle by the silicate bandage, 488; of hip-joint disease, 489; of traumatic tetanus with atropine, 497; of the vomiting of pregnancy, 511; of fungous arthritis, 516; of tinea tonsurans, 517; of hemorrhoids, 541.

Triangle, left carotid, removal of a fibro-cellular tumor from the, 68.

Trichinæ in hogs, 87.

Trick, the quinine, 110.

Trigeminal neuralgia cured by aconitia, 255.

Triplets and plural births, 553.

Trophic neuroses, 183.

Tropics, mortality in the, 220.

Troublesome parasite, 4.

Tube, Eustachian, diseases of the, 453.

Tuberculosis, the throat in, 407.

Tubular bandage, elastic, in treatment of eczema and ulcers of the leg, 247.

Twins in a primipara, 471.

Tumor; fibro-cellular, removed from the left carotid angle, 68; ovarian, 139; of lip, 427.

Tumors, fibroid uterine, treated by ergot, 315, 486.

Tumors; large ovarian, the diagnosis of, 61; adenoid, in the naso-pharyngeal cavity, 386.

Turpentine vapor, dangers from, 457.

Tying the cord, 58.

Tympanites, 271.

Typhoid fever; prevention of relapses in, 13; coffee in, 39; aphonia in, 42; the tongue in, 219; muriatic acid in, 232; sewer gas and, 249; the poison of, 261; digitalis in, 370; relapse in, 375; purgatives in the early stages of, 452; relation of age to, 524.

Typho-malarial fever, 334.

Typhus; abdominal and petechial, treated by the douche, 384; fever, 514.

Two; prize essays, 130; cases of puerperal convulsions, 200.

Ulcer; of the rectum; treated by dilatation, 62; a simple cure for, 109; varicose, 246; of the leg treated by elastic tubular bandage, 248; of the stomach, bromhydric acid in, 324.

Ulcers, iodoform and quinia in, 545.

Ulcerated os, bismuth in, 436.

Ulcerations in infants, 61.

Uncultivated people, nervous maladies of, 390.

Unguentum petrolei in eczema, 194.

Unlucky victory, an, 307.

Unprofessional testimony, 285.

Unsoundness, mental, a sign of, 83.

Urethra, male, stricture of the 199, 426.

Urinary diseases, maize stigmas in, 481.

Urine, incontinence of, 33.

Urticaria, 54, 82, 217, 238.

Use; of the forceps, 17; of iodine in dry asthma, 17; of spectacles, how to postpone it, 31; of damp cotton in place of the surgical sponge, 32; of carbolic acid in piles, 34; of croton-chloral, 84; of morphia, 106, 349, 410, 423, 431; of atropia, 167; of Fowler's solution in chorea, 388; of veratrum viride in diseases of the air passages, 400; of cold baths in enteric fever, 409; of pilocarpine, 436; of duboisia in eye diseases, 464; pharmaceutical, of gelatine, 474; internal, of tar, 532; of iodoform, 553.

Uterine; fibroid, 204; treated by ergot, 317; contraction, fracture of the fœtal skull from, 326; disease, nervous symptoms of 370; fibromas, treatment of, 385; instruments, Staufer's, 505.

Uterus; puerperal, partial inversion of the, 195; fungoid degeneration of the lining membrane of the, 354; effect of pilocarpine, eserine, etc., on the, 385; fibrous tumors of the, treated by ergot, 486.

Utility, doubtful, of the hot vaginal douche, 31.

Vaccination; items, 110; smallpox and, 457; animal, 131; Sir Thomas Watson on, 505.

Vaginal; douche, hot, doubtful utility of the, 31; lavements for vomiting of pregnancy, 217.

Vaginismus, treatment of, 166.

Value; of blistering, 57; of drug smoking in asthma, 253; of the melia azedarach, 282; of yerba santa in catarrhal affections of the upper air passages, 377; of the hypophosphites in phthisis, 387; of hyoscyamine in mental affections, 451; of calomel in the zymotic diseases of infancy, 474.

Valvular disease of the heart, veratrum viride in, 400.

Vapor of turpentine, dangers from, 457.

Varicocele, a new method of operating for, 343.

Varicose ulcer, 246.

Varieties; of psoriasis, 325; of quack medicines, 345.

Various; occupations, size of the head in, 347; methods in therapeutics, 455;

Vasomotor disturbances, 118, 188.

Venereal diseases, 536.

Vegetable neurotic, a, 172; kingdoms, limits of, 525.

Vehicle of infection, catgut as a, 255.

Venereal warts, 276.

Ventilation; of public and private buildings, 38; sub-earth, applied to hospitals, 291.

Ventral gestation, congenital, 72.

Veratrum viride; poisoning, 63, 167; in diseases of the air passages, 400.

Verrucous growth of the scalp, 56.
Version; combined external and internal, 84; spontaneous, 471; remarks on, 538.
Veterinary medicine; as a career for young men, 126; importance of, 217.
Victim of the quinine speculators, 175.
Victory, an unlucky, 307.
Vienna, results of treatment in, 175.
Villous disease of the bladder, 78.
Violent deaths, relation of intemperance and temperance to, 502.
Virchow on the germ theory, 61.
Vision, defective, produced by school life, 343.
Visiting list, physicians', 502.
Vitality of the teeth, 348.
Vomiting of pregnancy; treatment of, 18, 317, 511; vaginal lavements for, 217; iodine to the os in, 278; chloral in, 297.

Wales, Surgeon General, reception to, 505.
Want of rest, inebriety from, 268.
Washington training school for nurses, 417.
Warts, venereal, 276.
Wash in post-nasal catarrh, 523; in fetid coryza, 523.
Water supply of Philadelphia, 87.
Waters, natural mineral, as therapeutic agents, 27.
Watson, Sir Thomas, on animal vaccination, 505.
Weapons, rusty, refurbished, 481.
Wens, an easy method of removing, 4.
Western North Carolina for consumptives, 61.
What is hyalin? 552.
Whooping cough, combination in, 346.
Why; Hebrew reads from right to left, 502; scientific medicine recognizes no fixed laws, 544.
Wines of Egg Harbor, 307.
Winter and its dangers, 411.
Wire seton, in displaced retina, 76.
Wolfe's operation for cataract, 498.
Woman question, Dr. Yandell on the, 132.
Womb, hypertrophic elongation of the supra-vaginal portion of the neck of the, 463.
Women, diseases of, 411.
Worms, intestinal, a complication of intermittents, 86, 152.
Wounds; antiseptic treatment of, 33, 67, dressing for, 39, 210; of the abdomen, veratrum viride in, 400; rest, pressure and dry dressing in, 432.

Yellow fever, 65, 87, 133, 148, 175, 190, 212, 241, 272, 286 327, 330, 373.
Yerba santa, 377.
Young men, veterinary surgery a career for, 126.

Zulus, surgery among the, 285.
Zymotic diseases of infancy, value of calomel in, 474.

W. H. SCHIEFFELIN & CO.'S
SOLUBLE
PILLS AND GRANULES,
UNEQUALED FOR
Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

1. The best materials are used in their manufacture.
2. No article required by a formula is omitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.

Our list of Pills and Granules embraces those made according to the formulæ of the U. S. Pharmacopœia; also most of those in common use among the profession.

"MASTERLY INACTIVITY" IN THE TREATMENT OF DISEASE.

BY S. M. HAMILTON, M.D.,
Of Monmouth, Ill.

The bulk of our current literature is written from the standpoint of experience and observation in large hospitals. Our text books on theory and practice are, for the most part, deductions from clinical studies of cases treated in these institutions. While the importance of the matter thus obtained is acknowledged, we cannot resist the conviction that too little attention has been given to the fact that these were hospital patients, generally poor, ignorant, dirty, ill-fed, ill-clad, and poorly housed in their normal condition. That disease among such is very different in its requirements, as to treatment, from the same type of disease among the robust, well-fed denizens of the rural districts, no one can deny. No doubt acute disease of any description, originating in the slums and dirty lanes of a large city, would be decidedly atonic in its character, requiring sustaining treatment and stimulation from first to last. Indeed, the most careful clinical observation shows that this line of treatment is proper, generally, with such cases. But it would be well to remember that all cases are not like these; that nine-tenths of the world's people live outside of the large cities, and, as a class, require a radically different mode of procedure in the care of their sick. This, of course, would be assented to by all of our teachers and writers worthy of a name and place in our literature. Nevertheless, it is a fact that in their public utterances it is almost entirely ignored. It might be said, in excuse, that our teachers expect one to think for himself, and draw his conclusions as much in the light of his own as the experience of others. That he shall adopt a line of treatment according to the requirements of the particular case in hand. True; but unfortunately the habit of independent thought comes slowly and painfully to most men; to some never, and to all through much tribulation, of broken idols and disheartening failures. Most of our teachers, no doubt, steer as wide of dogma as could well be expected under the circumstances. But the truth is, they are not in a situation to realize the importance of this matter. Possibly it is not very pleasant for a learned and celebrated teacher to acknowledge before his pupils that the maxims which he has been laying down with such earnestness are results of observations extending over only a very small segment of the great circle of scientific truth.

One of the many evils inflicted upon our profession by this vicious mode of teaching and writing is that professional heresy very appropriately styled the "Let alone" plan of treatment. It is not claimed that the "expectant" mode of treating disease is always wrong; far from it. In some cases this is all that is left for the practitioner. But that it has the wide, almost universal, application claimed for it by many men in the profession, great and small, is undoubtedly a most mischievous heresy. Many of our most celebrated teachers and writers of to-day teach and write that nothing can be done in the way of aborting, or even shortening the duration of an attack of disease, under any cir-

c imstances ; that all diseases, including pleuritis and acute pneumonia, must run their allotted course ; and all we can do is to conserve the natural forces of the body against its influence. And then, if the patient has stamina enough to outlast the disease, he gets well. If not, not. Stripped of verbiage, this is the position of the so-called conservative school of practice now. After all the labor, energy and painstaking research, from the time of Galen and Hippocrates to the present, we have come to this "most lame and impotent conclusion," that we can do nothing. Beyond question, to Germany belongs the honor (?) of having originated this heresy. Certainly, the contributors to that exhaustive and *exhausting* work, "Ziemssen's Cyclopedia," lay down this law for all the world, with true German, hard-headed dogmatism. It reminds us of that other very learned German who studied and dreamed over "pipe and mug" so many years, and at last heralded to the world that all medicinal virtue and all curative power was contained in a small pellet of glucose, containing an infinitessimal atom of nothing. "Similia similibus curantur."

A fair specimen of this mischievous teaching is Juergensen's contribution to the aforementioned Cyclopedia, on the subject of pneumonia. He passes in dignified silence all authorities not German, and dismisses with a sneer of contempt all modes of treatment called "antiphlogistic," as entirely behind the professional advancement of the age. He seems to have constructed a little "Procrustean bed" at the little clinic of Keil, and asks, nay, demands, that the whole world squeeze itself into it. That cases of pneumonia are properly treated by stimulants from first to last is not denied. And Juergensen's cases in the clinic of Keil may all have been of this type, and were treated as they should be. It would seem, however, that the frightful mortality among his patients ought to have raised at least a doubt in his own mind as to the correctness of his views. But not so. He "lays down the law" that this is the best and only proper treatment for pneumonia.

The bane of the medical profession of to-day is empiricism in high places. Why should any man say that this or that is the way to treat pneumonia, scarlatina, typhoid fever, smallpox or measles, or anything else? It would be a happy day for us all if all generic names for diseases were struck out of existence. They are of no use, and only calculated to mislead the unwary. Names are nothing, conditions everything, in the treatment of disease. As it is, a man like Juergensen will report, say one hundred cases of pneumonia; says but little about the real diseased condition present, nothing as to their previous surroundings in their homes, nothing as to their previous health. They were admitted to the clinic of Keil, and had pneumonia, and were treated thus and so. What is the value of such reports as these? What are they worth as guides to the general practitioner outside the clinic of Keil or similar institutions? As a rule, plans of treatment based upon observations of disease as found generally in large metropolitan hospitals are valueless as guides when dealing with the same type of disease as it exists in the rural districts. It should be remembered that more than nine-tenths of the human family live outside the large cities, and that nine-tenths of our young physicians go into the country to practice. Our college professors should see to it that they are not misled by these false lights at the very opening of their professional career.

It is not the purpose of this paper to discuss the vexed question of malaria, or the causes operating in the production of our so-called "zymotic diseases." It is highly probable that the causation exists in almost as many forms, and in as great variety, as the cases themselves. Let this be as it may, all agree that there is a morbific poison of some kind, introduced into the circulation in some way, which produces the disease.

In nearly all cases there is a space of time in the commencement of the attack when the glandular system will respond to the effects of medication, and their excretory ducts carry off the products of secretion. Why should we not take advantage of this golden opportunity to get rid of at least a part of the poison which is circulating in the blood vessels, and destroying the life? It is true that no one can demonstrate to a certainty that he has aborted or cut short a case of disease, for he does not know what it would have been if left to itself; but the strong conviction that it has and can be done pervades the minds of thousands who are a little "offish" about asserting it, for fear of being considered old-fashioned. That there are an exceptional number of cases of disease, in certain epidemics, in which the powers of life are so suddenly stricken down that there is no time for such procedure, in which paralysis of all the secreting and excreting organs takes place in the very onslaught of the disease. In these, of course, there is little left but the sustaining and expectant treatment, and here is its legitimate field of operations ; a *dernier ressort*, when nothing else can

be done. It is not true that our warfare against disease should always be defensive. A vigorous attack upon the stronghold of the enemy will very often give the best results.

INVERSION OF THE BLADDER.

BY A. LANGWORTHY, M.D.,
Of Greenwich, N. Y.

Reading the cases reported in your journal, Feb. 1st and 8th, of "Inversion of the Bladder in Children," it occurs to me that possibly a history of a case in the adult might be of interest, and were it not that I object to the endeavor to rush into print with single cases of any special form of disease, it would probably have been previously written out.

During the summer of 1876 I was called to see a Mrs. B., of Tunkhannock, Rensselaer county, New York, for the purpose of diagnosis and prognosis; and upon arriving, after resting, it being a twenty-mile drive, proceeded to a careful examination of the patient.

The history of the case was a very usual one. Years of endometritis and disease of the cervix uteri, with its train of attendant ills; the case unattended to, from prejudice on the part of the lady to so-called uterine treatment with examinations; from the neglect, her nervous system becoming gradually broken down, her whole system lowered in tone and power, disease of the larynx and bronchia supervening, and tuberculosis fully developed and rapidly gaining ground, from loss of power of resistance.

The prognosis could, of course be but one way, unfavorable, and while life might be prolonged, yet even this result could only be transient, and life could last but a few months at best.

In a general conversation, she gave me a full and succinct history of the commencement and progress of her uterine troubles, and regretted she had not attended to them in time; but while she said she suffered "a great deal of straining, bearing down, and difficulty of micturition," declined to have a present examination, "as it was too late," and I, coinciding with her, did not insist upon it.

One week after I received a hurried message from her, requesting an immediate visit, she being quite alarmed, and saying "everything was coming down out of her."

An examination of this part of her body revealed, not a form, or any form of uterine displacement, or prolapsus, but the vaginal opening was covered with a blood-red tumor, tender, exquisitely tender, to the touch, angry and irritable. Not having with me any anæsthetic, and her agony being so great upon any attempt at manipulation, I, drawing in my mind a conclusion of some form of polypoid, advised soothing treatment, applications of heat, cosmoline and subnit. bismuth, for dressing, and agreed to remove it one week from that day.

Upon Sunday following I went again, and found the swelling but slightly tender, and the lady so comfortable, she had almost concluded to send word for me not to come. I proceeded to a careful diagnosis, proposing to operate with the ecraseur, or in whatever way seemed most applicable to the case. Examining carefully, raising it with my left hand (it was two inches by two and a half in size), I found it proceeded from the urethra, and upon questioning found that while there was frequent desire to urinate, and tormina and tenesmus of the bladder, yet the urine flowed quite freely; "it always made her strain so," she said, and "seemed as if she was never done;" she "had to stop while yet feeling the desire," etc.

Still more carefully inspecting the case, I saw that while the general mass was globular, yet I could detect upon its surface a set of apparently concentric rings, becoming smaller and smaller toward the centre. Looking at it, and studying upon its character, and the difference between it and the ordinary polypoids, a thought occurred to me; I took from my case a Sims catheter, and covering it well with cosmoline, placed the end upon the centre, as near as I could, and with a gentle push it entered the bladder, and the urine flowed freely; my diagnosis was, upon tracing it all around the catheter, complete. I had a case of inversion of the bladder.

Smearing my right hand thoroughly with the same grease, and gathering up the swelling, and manipulating it with the palm ends of the fingers, after forty minutes steady and careful manipulation I returned it all within the urethra, and with the forefinger in the urethra completely restored it to position.

The consequent relaxation of the urethral walls, and the still irritable condition, causing almost continual effort upon the part of the patient not to strain and try to urinate, led me to inject a few drops of morphia hypodermically; as an additional precaution I introduced a Sims catheter, and with adhesive straps fastened it to her body, and directed her to use cloths, to prevent accumulation in the bladder.

The case progressed very well, notwithstanding her otherwise critical condition, she experiencing no further trouble in this respect, up

to her death, which occurred a few months later, from her tuberculous disease.

The after treatment was simple. The catheter was left inserted for thirty-six hours; then the lady's daughter was taught its use, and used it at regular hours for one month. She was also taught how to insert, twice a day, a suppository of cocoa butter, containing gallic acid, in the urethra. This was all the special treatment to prevent the recurrence of the inversion.

A TROUBLESOME PARASITE.

BY C. H. SHIVERS, M.D.,
Of Haddonfield, N. J.

Madgie P., three years of age, whose home is in a neighborhood where, in the spring and fall, almost every case of sickness needs anti-malarial treatment, had been suffering, for seven or eight days, during last October, with a quotidian intermittent. After the old women's remedies had been exhausted I was sent for, and, as a matter of course, diagnosed the case malarial fever. The symptoms were—fever every afternoon, lasting until morning and followed by profuse sweats; bowels alternately constipated and relaxed; tongue somewhat dry and furred; continued thirst; disgust for all food except milk; rapid emaciation; extreme debility.

Never during my experience has a case presented itself which called more loudly, and plainly and persistently, for specific treatment. With emphatic assurances to the family that on the morrow, or at the furthest, the next day but one, their child would be transformed from this miserable state into something like its former self, I ordered the following, viz.:—

℞. Quiniæ sulphat., gr. xvj
Vini pepsini,
Syr. glycyrr., comp., āā. f. ℥j. M

Sig.—Teaspoonful every two hours, as directed.

Whether all physicians experience, at times, that "soft and subtle" consciousness—that "Mens sibi conscia recti"—steal upon them, and suffuse their inmost selves, I do not know; but at the time of writing the above prescription I felt it, and pictured to myself how pleased the parents would be to see their only child so soon relieved. My visit was made between breakfast and dinner. The next day, toward evening, I again visited my patient, and came upon her in the act of taking a dose of medicine, which, almost as soon as swallowed, was ejected. This had been the case, I was informed, every time it was taken. She had a high fever, which came on at the usual time, and all the symptoms were "In statu quo ante bellum." After giving orders to administer half the quantity of medicine, I left. Every day for two weeks my visits found the patient no better. Quinia, cinchonidia, cinchonia, followed by acid. hydrochlor. dil., and liq. potas. arsenit., with tinct. aconiti, liq. potas. cit., etc., during the fever, were given persistently, sometimes being retained and sometimes rejected by the stomach. Finally the child's parents were so emphatic in their denunciation of the "nasty medicine," that, having in mind a vision of homœopathy and its sweetness stepping into my shoes, I left some parvules of calomel, one-tenth of a grain each (prepared by Wm. R. Warner & Co.), to be given, one every two hours. The next day I approached the house with fear and trembling, expecting to find my little patient sinking. What was my joy and surprise on being greeted by the mother with, "Doctor, the baby is much better, and had no fever yesterday!" She, at the same time, handed me a tumbler containing a large *ascaris lumbricoides* (round worm), about five inches long, which the child had passed the day before, after taking three or four parvules. The nausea had also disappeared. After this I paid but three more visits, and the child speedily recovered.

AN EASY METHOD OF REMOVING WENS.

BY E. H. COOVER, M.D.,
Of Harrisburg, Pa.

About one year ago I was consulted as to the removal of a sebaceous tumor, just where the suspender crossed the shoulder. I explained to the patient the nature of the growth and the importance of having the entire cyst removed. He was not willing that much cutting should be done, but requested me to open and evacuate its contents. I then made a small opening into the sack, and pressed out its contents, by making sufficient pressure on the tumor to evacuate the sack. I discovered at the opening an accumulation of pulpy substance. I introduced a pair of small forceps, caught a fold of the sack, and with gentle traction removed it entire. The parts united, and a good cure was the result. I thought no more of this mode of operating until Feb. 25th, 1879, when Dr. Madden, of Baldwin, invited me to see and operate on a lady patient of his who was afflicted with a large wen over the occipital ridge. She was in delicate health, and was fearful she could not endure the removal of

the sack with the knife, but was exceedingly anxious to have something done with the growth, as it prevented her from lying on her back. I made an opening of half an inch, penetrating the sack here as in my first case, evacuated the contents, and removed the sack with little pain, in the short period of a few minutes. This is done very much as a boy kneads an orange when sucking its juicy contents from a small opening. By this kneading process the connections between the sack and surrounding integuments are broken and the sack becomes entirely loosened.

April 22d, 1879, I had an opportunity of repeating this mode of operating, in the removal of five of these sebaceous tumors, from the size of a common chestnut to that of a small hen's egg, from the heads of two persons, mother and daughter. I opened one after another, manipulating the same as in the other two cases, and in three of them was equally successful in removing the sack; these contained a thick, cheesy-like substance; the two last contained a thin fluid, with broken down cell walls; the sack in these was thin and brittle, coming away in pieces; the removal was more tedious and painful, but not near so difficult as it would have been to have dissected off the sack with a knife.

Hospital Reports.

GERMAN EYE AND EAR INFIRMARY, PHILADELPHIA.

SERVICE OF DR. M. LANDESBERG, SURGEON IN CHARGE.

833 Cases of Ear Diseases.

During the time of its existence, from July 30th, 1876, to December 31st, 1878, there have been treated in the German Eye and Ear Dispensary 833 ear patients, the different kinds of diseases of whom are described in the following clinical report:—

(*A*) EXTERNAL EAR.

(*a*) AFFECTIONS OF AURICLE.

1. *Eczema of auricle and of external auditory canal* was observed in 50 cases—in 14 men, 12 women, 13 boys and 11 girls.

The ages were as follows:—

Men.		Women.	
From 18 to 30 years,	7	From 20 to 30 years,	3
31 – 40 "	2	31 – 40 "	5
41 – 50 "	3	41 – 50 "	4
51 – 60 "	2		
Boys.		**Girls.**	
From 1 to 5 years,	8	From 1 to 5 years,	9
6 – 10 "	5	6 – 10 "	2

There were affected in both ears, 8 men, 7 women, 10 boys and 8 girls; in the right ear, 5 men, 2 women, 3 boys and 3 girls; in the left ear, 1 man and three women.

In 27 cases the disease affected the auricle only; in 23 cases it spread to the external auditory canal; in some cases the eczema occupied the surrounding parts of the ear, extending even to the head.

With the children the combination of eczema of the head and face was very often observed.

In the acute state of the disease I ordered, with the best result, applications of 20 drops of liquor plumbi subacetici in a cup of warm water, and when the inflammatory symptoms had subsided I gave an ointment of white precipitate to be rubbed on the affected parts twice a day, besides ablutions with warm water and soap. Under this treatment even the most neglected cases were cured, if the patients continued the use of the ointment as long as there existed any signs of inflammation of the skin. The liability to relapse is very great, and the relapse mostly occurs in patients who, satisfied with the good primary result of the ointment, neglect its further application.

2. *Othæmatoma* of the right auricle was observed in the case of a laborer's wife, 23 years old. She suffered from otitis externa of the left ear, with great swelling of the soft parts. The general health of the woman was perfectly good. The othæmatoma presented a tumor of the size of a walnut, occupying the middle of the concave surface of the auricle. It was of a bluish-red color, and doughy to the touch. There was no assignable cause of its development. There had been no traumatic lesion. Incision evacuated dark, coagulated blood, bringing perfect restoration without the least disfigurement of the auricle.

3. *Nævus* of the auricle was observed in the cases of two children, aged respectively 2 and 5 weeks. In both cases the affection was congenital. In one case the nævus occupied the right ear lobe, in the other the concave side of the right auricle. They were very small, flat, and circumscribed. I abstained from therapeutics.

4. *Telangiectasis* of the auricle was observed in two cases, *viz.*:—

(I) Of a shoemaker's boy, 3 years old, on the anterior surface of the left helix.

(II) Of a laborer's daughter, 9 months old, on the anterior surface of the left ear lobe.

In both cases the telangiectasis were flat, of slight extension, and developed post-partum. In the first case telangiectasis was removed by the injection of a weak solution of sesquichloride of iron; in the second case by vaccination.

5. *Tumors*—fibroma— of the auricle were observed in two cases, viz.:—

(I) A laborer's wife, 48 years old. Tumor of the left auricle, of the size of a pigeon's egg, occupying the middle between the helix and concha, of firm, slightly elastic consistency, immovable and covered with healthy skin. The tumor was of slow growth, covering the space of 17 years. In the last two years, when the menses stopped, the tumor progressed very rapidly to its present condition. No pain. General health good.

I made an incision of the skin through the whole length of the tumor, enucleated it, cut off the redundant skin flaps, and closed the wound by sutures. Healing per primam.

(11) Tanner's wife, 43 years old, sister of the former. Fibroma, of the size of a walnut, in the inferior third of the left auricle, between the helix and concha. Skin normal. Growth of two years. General health good. I made the same operation as above described, with the same result.

6. Split ear lobes were observed in a smith's daughter, 2 years old, caused by wearing ear rings. My method of operating was like that recommended by Knapp (Archives for Ophthalmology and Otology, vol. III, 2). It is an operation based on the method pursued by Langenbeck in hare-lip. The result was a very fine one.

(*b*) AFFECTIONS OF THE EXTERNAL AUDITORY CANAL.

1. *Diffuse inflammation of the external auditory canal* (*otitis externa*) was observed in 104 cases—in 46 men, 26 women, 15 girls and 17 boys.

The ages were as follows:—

Men.		Women.	
From 18 to 30 years,	21	From 18 to 30 years,	13
31 – 40 "	6	31 – 40 "	5
41 – 50 "	8	41 – 50 "	2
51 – 60 "	7	51 – 60 "	3
61 – 70 "	4	61 – 70 "	3
Girls.		**Boys.**	
From 3 to 5 years,	7	From 1 to 5 years,	6
6 – 11 "	8	6 – 10 "	7
		11 – 15 "	4

There were affected in both ears, 30 men, 14 women, 4 girls and 8 boys; in the right ear, 8 men, 7 women, 6 girls and 5 boys; in the left ear, 8 men, 5 women, 5 girls and 4 boys.

A frequent cause of inflammation of the external auditory canal of adults was cold river bathing in the hot days of July and August. Also in other seasons exposure to cold was the main cause of this trouble.

The children were brought to me mostly in a very neglected condition, with offensive, nauseous discharge. Here the affection was in many cases the consequence of scarlatina and measles, but in others no cause could be ascertained.

In three cases of men, otitis externa was complicated with myringitis.

The treatment was antiphlogistic in cases of acute inflammation. If there was discharge, the ear was carefully syringed twice a day with lukewarm soap water, in combination with the use of a solution of carbolic or salicylic acid, and of astringents.

2. *Circumscribed inflammation of external auditory canal—furuncle*—(otitis externa circumscripta) was observed in 26 cases—in 14 men, 10 women, 1 girl and 1 boy.

The ages were as follows:—

Men.		Women.	
From 20 to 30 years,	6	From 17 to 25 years,	7
31 – 40 "	5	26 – 30 "	3
50 – 60 "	3		

The girl was 11 and the boy 8 years old.

There were affected in both ears, 1 man; in the right ear, 8 men, 7 women, and 1 boy; in the left ear, 5 men, 3 women, and 1 girl.

In the early state of the affection I succeeded sometimes in checking its further development by cauterizing the furuncle with nitrate of silver (abortive treatment of Wilde). In all other cases the treatment consisted in making a deep incision through the furuncle and fomenting it with warm water. In a couple of cases, where patients would not allow incision to be made, the furuncle was brought to suppuration by application of hot poultices.

3. *Impacted cerumen in the external auditory canal* was observed in 105 cases—in 67 men, 24 women, 6 girls and 8 boys.

The ages were as follows:—

Men.		Women.	
From 20 to 30 years,	24	From 20 to 30 years,	7
31 – 40 "	16	31 – 40 "	6
41 – 50 "	12	41 – 50 "	5
51 – 60 "	10	51 – 50 "	6
61 – 65 "	5		
Girls.		**Boys.**	
From 11 to 15 years,	6	From 5 to 14 years,	8

There were affected in both ears, 36 men, 11 women, two girls and 5 boys; in the right ear, 20 men, 7 women, two girls and two boys; in the left ear, 11 men, 6 women, 2 girls and 1 boy.

With one exception, the patients complained of sudden or gradual decrease of hearing, of pressure and noise in the ears. In many cases the loss of hearing was so great that patients could hardly understand a loud voice close to the auricle. These symptoms disappeared as soon as the cerumen was removed. But normal hearing was not always restored. There remained thickening and opacity of the tympanic membrane, which impaired hearing.

In the case of a shoemaker's wife, fifty years old, impacted cerumen was the cause of intense pain in the interior of the ear, irradiating to the head and all over the face, and of repeated attacks of oppression and vertigo. The affection had lasted already eighteen months, making the patient very nervous and prostrated. She had been treated all this time as suffering from nervous disease consequent upon suppression of the menses. The examination of the external auditory canal showed it to be filled up to the opening with a dark brownish matter, firmly packed together. After the impacted cerumen was removed, the patient was at once totally relieved from all fits of giddiness, nervous attacks and pain.

For removing impacted cerumen, I never use any instruments. Carefully syringing with lukewarm soap water, adding sometimes an alkaline solution to be dropped into the external canal, I always succeed in bringing about the desired result. If, after the removal of the cerumen, there is still some noise in the ear, I use for some time Politzer's bag. If there is soborrhœa I treat it by astringents.

4. *Soborrhœa of external auditory canal* of both ears was observed in 10 cases—in 4 men (aged respectively 18, 21, 33 and 46 years), 3 women (from 20 to 25 years), 2 girls (aged respectively 14 and 15 years), and 1 boy, 13 years old.

The treatment consisted in cleansing the canal with lukewarm soap water, and administering astringents.

5. *Diminished secretion of cerumen* was observed in 6 cases—in 4 men (from 30 to 45 years), and 2 women, aged respectively 41 and 59 years.

There were affected in both ears 3 men; in the right ear, 1 man and 1 woman; in the left ear, 1 woman.

The patients complained of a very disagreeable itching in the auditory canal. This was found to be red, bloody and dry. The patients generally aggravated the affection by scratching their ears with hairpins, nails, etc., in order to appease this itching.

The use of an alkaline solution to be dropped into the ear several times a day, and the inunction of cosmoline, always led to perfect recovery if patients could be prevented from further irritating the ears.

6. *Polyps of external auditory canal* were observed in 11 cases—in 2 men (27 and 35 years old), 6 women (from 30 to 45 years), and 3 girls (aged respectively 10, 12 and 14 years).

There were affected in both ears, 4 women; in the right ear, 2 men, 2 women and 1 girl; in the left ear, 2 girls.

In two cases polyps filled up the whole canal.

The treatment consisted in removing the polyps by means of Wilde's aural polypus snare, cauterizing afterward the remaining parts with nitrate of silver, or applying tincture of opium.

7. *Foreign bodies in the external auditory canal* were observed in seven cases, viz:—

(1) Saloon keeper's son, 4 years old. Pebble in the left canal.

(2) Shoemaker's son, 7 years old. Paper ball in the left canal.

(3) Barkeeper's daughter, 8 years old. Bean in the left canal.

(4) Laborer, 25 years old. Pea in the right canal, forced in by way of playfulness.

(5) Musician's son, 6 years old. A piece of slate pencil in the left canal.

(6) Laborer's daughter, 9 years old. Glass pearl in the right canal.

(7) Seamstress, 19 years old. Cotton ball in the right canal.

The latter patient came to me complaining of noise in the right ear, hard hearing and temporary giddiness and neuralgic pain. Examination of the ear showed the external auditory canal filled up with a brown matter. Supposing I had to deal with impacted cerumen, I ordered the ear to be syringed with lukewarm soap water for a couple of days. Patient followed my advice very conscientiously, but without any success. On examining the substance with a probe, it proved to be somewhat hard. Introducing the knee forceps into the canal, I succeeded in removing at once the whole mass, a cotton ball with cerumen. The patient was very much astonished to see this corpus delicti. She remembered that some years ago she had toothache, for which she put into the ear some cotton with cologne water, acknowledging the possibility of having forgotten the removal of it. Perfect recovery soon set in.

At first I never used extracting instruments for removing the foreign body, but applied injections of lukewarm water. In the majority of cases (2, 3, 4, 6) I succeeded in bringing the foreign body so far in front as to be able to remove it with the forceps. In the cases of 1 and 5 extracting instruments had to be used, the foreign bodies being too deeply seated in the auditory canal.

8. *Stenosis of the external auditory canal* was observed in two cases, viz.:—

(1) Car driver, 49 years old. Stenosis of the left auditory canal, the result of a scald. The smallest speculum could not be introduced. Could hear whispering at two feet distance.

(2) Laborer, 67 years old. Stenosis of the right auditory canal, gradually developed without any assignable cause. The canal was so narrow that only a very fine probe could be introduced into it. Could hear whispering at five feet. No syphilitic history.

In both cases no therapeutics.

(*c*) AFFECTIONS OF THE MEMBRANA TYMPANI.

1. *Acute myringitis* was observed in 11 cases—in 9 men, 1 woman and 1 boy.

The ages were as follows:—

Men.	Woman.	Boy.
From 20 to 30 yrs., 5	28 yrs. old.	10 yrs. old.
40 – 50 " 4		

There were affected in both ears, 2 men; in the right ear, 5 men and 1 woman; in the left ear, 2 men and 1 boy.

In all cases the affection was caused by exposure to cold.

Therapeutics were antiphlogistic. Hydropathic applications during the night proved to be most effectual to relieve pain and to check the progress of the affection. In 5 cases paracentesis of the membrana tympani was made.

2. *Lesions of the membrana tympani* were observed in 5 cases, viz.:—

(1) Machinist, 23 years old. Rupture of the left membrane, in its anterior half, consequent upon a blow.

(2) Laborer, 31 years old. Rupture of the right membrane, parallel with the malleolus, consequent upon a cannon shot discharged near the person, July 4th, 1877.

(3) Plumber, 51 years old. Rupture of the right membrane, along the malleolus, following the discharge of a pistol, July 4th, 1878.

(4) Smith, 44 years old. Rupture of the left membrane, in its anterior part, caused by a pointed nail introduced to scratch the ear.

(5) Tailor's daughter, 15 years old. Rupture of the left membrane, in its anterior half, caused by a knitting pin, with which the girl was accustomed to scratch her ear.

All these cases came fresh to my observation.

Closing the ear with cotton produced perfect recovery without any other treatment.

3. *Lime incrustation of the membrana tympani* was observed in 8 cases—in 6 men (from 50 to 63 years) and two women (aged respectively 57 and 69 years).

There were affected in both ears, 2 men; in the right ear, 4 men; in the left ear, 2 women.

The symptoms were noise in the ear and impairing of hearing.

The air douche was tried, without much benefit.

(*B*) AFFECTIONS OF THE MIDDLE EAR.

1. *Acute catarrhal inflammation of the middle ear (otitis media acuta)* was observed in 23 cases—in 15 men, 6 women and 2 boys.

The ages were as follows:—

Men.		Women.	
From 17 to 30 years,	7	From 18 to 30 years,	4
31 – 40 "	5	40 – 49 "	2
41 – 45 "	3		

Boys.

From 10 to 15 years, 2

There were affected in both ears, 7 men, 2 women and one boy; in the right ear, 5 men and 3 women; in the left ear, 3 men, 1 woman and 1 boy.

In all cases exposure to cold was the cause of the affection.

The treatment consisted in antiphlogosis, cathartics, paracentesis of the tympanic membrane, and hydropathic applications for the night. After the inflammatory symptoms had subsided, I applied Politzer's bag or air douche.

Paracentesis is the most heroic remedy in this affection, of the same consequence as iridectomy in glaucoma. At first I was rather a little too timid with the employment of paracentesis, but in the course of time I regarded it as the first indication in all cases of acute inflammation of the middle ear.

2. *Chronic catarrhal inflammation of the middle ear* was observed in 142 cases—in 74 men, 49 women, 6 girls and 13 boys.

The ages were as follows:—

Men.		Women.	
From 18 to 30 years,	15	From 20 to 30 years,	9
31 – 40 "	17	31 – 40 "	10
41 – 50 "	13	41 – 50 "	11
51 – 60 "	19	51 – 60 "	10
61 – 70 "	7	61 – 70 "	9
71 – 75 "	3		

Girls.		Boys.	
From 10 to 15 years,	6	From 9 to 15 years,	13

In 16 cases (of 8 men, 7 women and 1 boy) the disease affected one ear; in all other cases both.

The patients came mostly under observation after years of suffering, after having tried in succession all other dispensaries. From the majority of the patients exposure to cold was ascertained as the cause of the affection. With many there was hereditary disposition to chronic catarrhs of the middle ear. 11 men and 4 women were suffering from tuberculosis. 7 men and 2 women stated to have previously suffered from syphilitic affections. Of the children, diphtheria had occurred in three cases, and inflammation of the parotid in one case.

This class of patients is the great bore of the dispensary. Many, who by due patience and perseverance would have attained at least an improvement of their condition, cannot be induced to undergo a regular treatment. They are careless in following medical advice, discontented even if there is any improvement, because it is so slow, and give up the treatment after a week or two, to abuse another dispensary.

In some cases of so-called "catarrhus siccus" of the middle ear, where the nervous symptoms, especially the ringing and tinnitus, are so excessive that the condition of the patients borders almost on mental derangement, I obtained great relief by drawing, with Sigle's pneumatic otoscope, the membrane outward.

"Catarrhus siccus," with nervousness and hysteria, I often met with in female patients, especially old maids. They regard hysteria and nervousness as the primary disease, the ear affection as secondary only, in which opinion they are generally confirmed by the foregone treatment.

In two cases of chronic catarrh of the middle ear (seamstress, forty-two years old, and housekeeper, fifty-three years old), where noises in the ear were so troublesome and the patients so restless that mental derangement was to be apprehended, I made paracentesis of the tympanic membrane. In the case of the seamstress, the noise subsided immediately after operation, and the patient felt like a newborn. But already on the fifth day after the operation tinnitus returned, first slightly, then gradually increasing, notwithstanding the perforation of the tympanic membrane was kept open for six weeks. In the other case of paracentesis of the membrane there was but little improvement, and the patient, being of very gloomy mood, gave up further treatment, despairing of any relief.

In many cases of "catarrhus siccus," I introduced, by means of the catheter, into the middle ear, 2–3 drops of a solution (1 : 30) of hydrate of chloral, but without much avail.

(3.) *Catarrh of the Eustachian tubes and throat* was observed in 136 cases—in 76 men, 47 women, 5 girls and 8 boys.

The ages were as follows:—

Men.		Women.	
From 18 to 30 years,	26	From 21 to 30 years,	26
31 – 40 "	23	31 – 40 "	15
41 – 50 "	10	41 – 50 "	6
51 – 60 "	8		
61 – 70 "	9		

Girls.		Boys.	
From 6 to 10 years,	2	From 8 to 12 years,	4
11 – 15 "	3	13 – 15 "	5

In all cases the disease affected both ears.

In three cases, of a laborer, thirty-nine years old, and of two girls, aged respectively twenty-one and twenty-four years, the affection was of a syphilitic nature.

With the children the affection set in after diphtheria.

Hereditary disposition could be ascertained in 9 cases.

In nearly one-third of the adults there was either catarrh of the nose, or real ozæna, with offensive discharge and chronic hoarseness.

In fifteen cases of the adults there was real granulosis of the throat.

In one case (railroad officer, forty-one years old) there was congenital hare-lip and cleft palate.

With men the affection is often observed in consequence of tobacco chewing, which is very hard to cure, because people cannot be induced to give up their bad habit.

This affection is not of an absolute unfavorable prognosis, even in its chronic condition, if under proper treatment. We then succeed not only to check the disease, but also to bring about a great improvement. Certainly the treatment is a protracted one, demanding as well from the physician as the patient the greatest attention and perseverance.

First we must take into consideration the causal indications. The treatment of the nose and the throat is the first step. For the nose, it consists of cleansing it with lukewarm soap water (in cases of ozæna), combined with snuffing of a solution either of kali chloricum or kali hypermanganicum, or liq. natr. hyperchlor., or acid carb., etc., or touching the mucous membrane with nitrate of silver. The throat must be treated by astringent gargles or by local applications of a solution of nitrate of silver, and in cases of granulosis by applying sulphate of copper in substance.

If the glands are too hypertrophied they have to be excised.

The direct treatment of the ears consists in the air douche. The improvement of the hearing depends upon the improvement of the catarrhal affection of the throat.

4. *Acute purulent inflammation of the middle ear* (*otitis media purulenta acuta*) was observed in 7 cases—in 1 man, 44 years old, suffering from the right ear; in 2 women, aged respectively 19 and 21 years, suffering from the right ear, and in 4 children, from 3 to 8 years, of whom 3—2 girls and 1 boy—suffered from the left ear and 1 boy from the right one.

Both the man and the woman are stated to have suffered some time previously to their present affection, from tinnitus, pain in the ear and impairment of hearing. We had here probably to deal with a subacute or chronic form of affection of the middle ear, which increased to acute purulent inflammation. Its symptoms were very violent. Great lancinating pain through the head, tenderness of the surrounding parts of the ear to the touch, etc.

With the children there was no assignable cause of the affection. It came suddenly, breaking out mostly in the night, when the children awoke with great pain in their ear, and by their complaints caused the parents to suppose that there was an affection of the brain.

In five cases I at once made a paracentesis of the tympanic membrane, which resulted in immediate relief. The further treatment consisted in applying leeches before and behind the ears, in cathartics and hydrate of chloral for the night. After the acute inflammatory symptoms had subsided, I used the air douche with the adults and Politzer's bag with the children.

With two children I was prevented from making paracentesis of the membrane. By acute mercurialization I succeeded in checking the morbid process and bringing about a satisfactory result.

5. *Chronic purulent inflammation of the middle ear* (*otitis media purulenta chronica*) was observed in 136 cases—in 51 men, 38 women, 22 girls and 25 boys.

The ages were as follows:—

Men.		Women.	
From 18 to 30 yrs.,	24	From 18 to 30 yrs.,	19
31 – 40 "	13	31 – 40 "	8
41 – 50 "	6	60 – 65 "	11
51 – 60 "	5		
60 – 65 "	3		
Girls.		**Boys.**	
From 4 to 10 yrs.,	9	From 2 to 5 yrs.,	7
11 – 15 "	13	6 – 10 "	14
		11 – 15 "	4

There were affected in both ears, 30 men, 18 women, 11 girls and 12 boys; in the right ear, 13 men, 13 women, 5 girls and 8 boys; in the left ear, 8 men, 7 women, 6 girls and 5 boys.

Of the 136 cases, 15 men and 13 women were not fit for any treatment whatever. The affection was very old; the hearing totally lost; the membrane more or less destroyed, connected by cicatricial tissue with the promontorium, or it was opaque, concave, full of scars and of irregular shape.

All other cases showed perforation of the membrane.

In the children the affection was caused by measles and scarlatina in 22 cases, by meningitis cerebro-spinalis in 3 cases, by diphtheria in 4 cases. In the other the cause could not be ascertained.

As to the cause of the affection in adults, the examination gave the following result:—

1. From child disease in 28 cases.
2. From typhoid fever in 8 cases.
3. From tuberculosis in 7 cases.
4. From exposure to cold in 20 cases.
5. From smallpox in 12 cases.
6. From scrofulosis in 14 cases.

Otorrhœa is an affection which the patients generally mind but very little, especially if it is one sided, or if the hearing is not very much affected. On the contrary, the discharge is regarded as a very useful excretion, removing from the body the morbid humors, and thus protecting it from various diseases. This opinion is met among all classes of people. They take care not to have the discharge stopped, lest it should happen to them as to their acquaintances, who enjoyed health and hearing as long as the discharge was continuing, but who lost their hearing or died from brain disease as soon as the discharge was stopped. Such patients come to the physician only if the discharge becomes very offensive or the hearing very hard, or if the chronic condition becomes acute. How little these people care for otorrhœa I very often observed with patients who apply for relief because the other hitherto healthy ear had been affected. They never mention the old affection, and if their attention is drawn to the fact of their suffering very seriously from the other ear, they will answer that there is only a discharge, which does not affect them at all, and that they do not like to have it stopped. It is labor lost to try to convince them of the danger of their condition. They will never use the prescription, and will lose the good opinion they may have had of the physician.

In many cases I met with very large defects of the tympanic membrane, in which either promontorium or the ossicles could be seen.

Double perforations of the tympanic membrane I saw in the following cases:—

(1) Laborer's daughter, 14 years old. *Right ear.* Perforation near the malleolus, connected by a small bridge of tissue.

(2) Shoemaker's daughter, 4 years old. *Right ear.* Perforation on the upper and under part of the membrane.

(3) Peddler, 44 years old. *Right ear.* Perforation on either side of the malleolus.

(4) Laborer, 29 years old. Perforation upward and downward of both ears.

The otitis purulenta chronica I found complicated with—

(1) Granulations in the middle ear in 7 men, 9 women and 4 children.

(2) Polypus in the middle ear in 5 men, 3 women and 3 children.

(3) Caries of the petrous bone in 3 men and 1 woman.

(4) Affection of the mastoid process in 2 men and 2 children.

(5) One-sided paralysis of the face in 3 men.

Necrotic elimination of cochlea I observed in the following case:—

D. B., laborer, fifty-nine years of age. Deaf in the right ear, consequent upon otitis media purulenta chronica. Nearly total destruction of the tympanic membrane. Tympanic cavity occupied by cicatricial tissue. In the left ear there was a small rim of the tympanic membrane remaining, and very copious discharge. Patient can hear only very loud voice close to the auricle. Hardly any perception of the tuning fork. Patient told me that now and then small particles of bone are discharged from the ear. I asked him to bring me every particle which might come out. Some days afterward he brought me a mass, which had been discharged from the ear. It proved to be *the whole cochlea, with a part of the labyrinthine wall of the vestibule, the oval window, and stirrup and anvil.* Loss of hearing was not increased thereby.

As long as there is no deeper-seated affection, as caries of processus mastoideus, os petrosum, or inflammation of the meninges, the prognosis in cases of otitis media purulenta is not absolutely unfavorable; it is much better than in cases of otitis media chronica. Neither the long duration of the affection nor the high impairment of hearing should make us despair of some relief. Even in the most neglected cases treatment may produce much benefit, and the power of hearing be much improved.

Treatment in chronic cases consisted in cleansing the ear very carefully with lukewarm soap water, in using an antiseptic solution of salicylic acid, in instilling a strong solution of nitrate of silver, and in the air douche. In subacute cases antiphlogistics were added.

The best method of treating otorrhœa is the use of a strong solution of nitrate of silver (1:8) 10–15 drops of which should be instilled twice a day into the ear, after having cleansed it very carefully. The drops must be kept in the ear for some minutes. If there is any pain, patients are allowed to wash out the ear with pure or salt water.

In cases of granulations I touched them with nitrate of silver, and polyps I removed with Wilde's aural polypus snare.

In cases of affection of the mastoid process I succeeded, by a deep post-auricular incision (Wilde's) through the swelling parts down to the bone, in checking the morbid process.

6. *Foreign body in the tympanum* I found in the following case:—

D. G., shoemaker's daughter, thirteen years old, was brought to me suffering from great pain, tinnitus and discharge of the left ear for about five weeks. After having cleansed the auditory canal, I saw a central perforation of the tympanic membrane, and in the tympanum near the perforation a foreign body of metallic lustre. The girl being very quiet and patient, I succeeded at once in extracting the foreign body, by means of knee forceps. It proved to be a metallic glove button. How it came into the ear, or how long it had remained there, could not be ascertained.

The morbid symptoms subsided at once; discharge was stopped with strong solutions of nitrate of silver. Perforation of membrane remained, without much impairment of hearing.

7. *Carcinoma medullare, growing out of the middle ear*, was observed in the following case:

G. E., servant girl, forty years old, is suffering from a tumor of the left ear, which began to grow out of the auditory canal about three years before, very slowly at the beginning but rapidly in the last year. At first pains were slight and intermittent, now they are very severe and permanent. Hemorrhages very often set in, which are stopped with great difficulty.

Present State.—Patient is very feeble and livid. There is complete facial paralysis of the right side. An uneven, dirty-reddish hard substance, slightly elastic, with abundant blood vessels, occupies the auditory canal and the whole circumference of the auricle, towering above it as big as a fist, with dirty-greenish, ragged surface. The tumor is slightly movable. The region of the mastoid process and of the os zygomaticum is swollen, œdematous, very painful on pressure. During the examination there arose from the depth of the tumor a large arterial hemorrhage, which was stopped only after considerable trouble.

(*C*) AFFECTIONS OF THE INNER EAR.

1. *Menière's disease* was observed in two cases, viz.:—

(1) W. R., brush maker, fifty-one years old, began in September, 1876, to suffer from slight attacks of headaches, with dizziness and tinnitus, in the intervals of which he felt perfectly well, and the power of hearing was unimpaired. In the evening of November 3d, 1876, he had an attack of such violent vertigo that he fell down, losing consciousness and vomiting several times. In the first days succeeding this attack vomiting occurred repeatedly, vertigo and tinnitus of the right ear were very violent, and giddiness so great, that as often as the patient tried to get up he reeled and fell to the left side. He remained in bed for several weeks, being treated, according to his description, as if suffering from congestion of the brain. The condition improved so far that giddiness somewhat abated, and he became enabled to get up and to walk a little, though with great precaution. When he came under my notice, in January, 1877, his state was as follows:—

The patient, a strongly built man, but pale looking, complains of violent humming and rushing, like the noise of a water fall, in his right ear. He walks very cautiously, with downcast eyes. Before making a step he first looks to the ground, touching it with his cane. But even in this cautious manner of walking his body is turned to his left side. Upon my request he tried to walk without using his cane as a

guide, and without looking to the ground, but at the first step his body turned to the left, falling to the ground. When his eyes were closed he was not able to stand erect; his body began to tremble and to incline to the left. If the patient stands, the body is turned with its axis to the left.

With his right ear the patient hears only very loud voice close to the auricle. Tuning fork not heard. Tympanic membrane somewhat dim, but otherwise in good condition. No pain. Surrounding parts of the ear normal. Sensibility and mobility of the face not impaired.

The left ear is normal.

The eyes are perfectly normal, with Hm. $\frac{1}{36}$ and V. $= \frac{20}{20}$.

Appetite is good, bowels are regular, mental functions slower than formerly; great tendency to drowsiness.

No syphilitic history; no assignable cause of the affection.

A therapeutic trial had no effect whatever.

(2) R. G., chemist, 40 years old, has suffered for about 20 years from otorrhœa of his right ear, without having been much troubled by it. On March 3d, 1878, the patient was suddenly taken by an apoplectic fit, during which he lost consciousness. In the following days vomiting often occurred. The hearing of both ears diminished very much, and violent tinnitus and noise, like a waterfall, set in in the right ear. In a horizontal position the patient did not feel any dizziness, but as soon as he tried to get up he felt as if all objects began to turn round about him from the right to the left side. Besides, there was violent headache, impairment of memory and paralysis of the face. On treatment, the general condition was somewhat improved.

When I saw the patient August 12th, 1878, his state was as follows:—

The right ear has only peripheric rudiments of the tympanic membrane; tympanum full of granulations, with little discharge. Mastoid process painful on pressure. Only very loud voice can be heard close to the auricle. Tuning fork not heard.

The left ear shows a central perforation of the tympanic membrane, without any discharge. Whispering heard at one foot distance. Normal perception of tuning fork.

No trace of paralysis of the face. Mucous membrane of the throat inflamed and swollen. There is a general tremor. The right leg is dragged in walking, and of less sensibility.

Patient is complaining of violent noise, like a waterfall, in his right ear, of swooning fits, dizziness, headache, impairment of memory and mental functions. He is still very liable to fall to his left side, especially in the dark, and the objects seem to turn from the right to the left. The balance of the patient is unsteady, with the axis of the body inclined a little to the left. When the eyes are closed the body begins to tremble more perceptibly, turning more and more to the left, until it is jerked totally to the left.

The eyes are normal.

The treatment of the affection of the right ear, consisting in touching the granulations with nitrate of silver, in cleansing the canal with lukewarm soap water and applying heurteloups to the mastoid process, combined with gargles and cathartics, effected in a short time such a great improvement that there was the best hope of perfect recovery. In this condition, the patient resolved to return to Germany, to his parents, where he could take more care of his health.

2. *Nervous hard hearing or deafness consequent upon mechanical commotion of the auditory nerve.*

(*a*) *Hard hearing consecutive to the report of firearms*, in the following cases:—

(1) B. H., weaver's wife, seventy-three years old, came to me a week after the report of a small gun had struck her left ear. Immediately after the accident violent hammering and ringing, with a sensation of fullness in the ear, set in. During the week the ringing abated somewhat, but there remained violent noise, like the rushing of a locomotive, dizziness and impairment of hearing.

The examination showed—

Right ear.—Whispering at 15 feet distance. Tympanic membrane normal.

Left ear.—Hears loud voice close to the auricle. Examination negative. Ear can be inflated by means of Politzer's bag, but there is no improvement of hearing.

Heurteloups applied to the mastoid process; cathartics gave but little improvement.

(2) S. R., tailor, forty-one years old, hears very loud voice close to the auricles; is complaining of tinnitus and noises in both ears. He served as cannoneer in the great rebellion, and got his ear affection by the discharge of a cannon, in the winter of 1863. Examination of the ears negative.

(3) F. A., merchant, forty-nine years old, felt, immediately after a small cannon had been discharged close to his face, rushing and ringing of both ears, dizziness and pressure in his head. When I saw the patient, six days afterward, he heard with either ear whispering at 1 foot distance. Perception of tuning fork was normal, and both ears gave good passage to the air douche. Tympanic mebrane normal.

Cathartics and drawing the membrane outward with Sigle's pneumatic otoscope gave perfect recovery.

(*b*) *Deafness consequent upon a box on the ear*, in the following case:—

T. C., laborer, fifty-eight years old, was struck senseless to the ground by a blow on his left ear. For two days he remained in an unconscious condition, vomiting several times. After recovering his senses his left ear was totally deaf.

When I saw the patient, nine days afterward, he hardly heard the loudest voice close to his left auricle. No perception of tuning fork. Tympanic membrane normal. No paralytic symptoms whatever. Right ear normal.

A therapeutic trial produced no effect.

(*c*) *Deafness consequent upon falling on the head*, in the following cases:—

(1) E. O'H., ragman, fifty-seven years old, lost hearing in his right ear by a fall on his head from the second story, three years previously. Whether there had been any lesion of the skull could not be ascertained. There is absolute deafness of the right ear, without any morbid symptoms. No therapeutics.

(2) M. T. Smith, forty-six years old, absolute deafness of both ears, caused by a fall from a tree, ten years previously. No lesion of the skull could be found out. Examination was negative. No therapeutics.

3. *Nervous hard hearing or deafness consequent upon affections of singular parts or organs of the body, or upon diseases of the whole organism, with negative result as to the examination of the ear.*

(*a*) *In consequence of typhoid fever*, in—

(1) Laborer's wife, 45 years old. Left ear absolutely deaf.

(2) Carpenter's son, 12 years old. Deaf in both ears.

(3) Laborer, 61 years old. Both ears can only hear a loud voice close to the auricles.

(4) Carpenter, 30 years old. Right ear hears a loud voice at 1 foot distance. Left ear hears a medium loud voice close to the auricle.

(5) Seamstress, 53 years old. Deaf in both ears.

(6) Tailor's wife, 69 years old. Right ear hears medium loud voice close to the auricle. Left ear hears medium loud voice at 4 feet distance.

In all cases there were subjective noises of the ears.

(*b*) *In consequence of meningitis cerebro-spinalis*, in—

(1) Carpenter's son, 8 years old. Deaf in both ears for three years.

(2) Saloon keeper's son, 9 years old. Deaf in both ears for two years.

(3) Tailor's daughter, 11 years old. Deaf in the right ear. Left ear hears a medium loud voice close by.

(*c*) *In consequence of scarlatina*, in—

Hair dresser's daughter, 14 years old. Deaf in both ears.

(*d*) *In consequence of tabes dorsalis*, in—

Merchant, 51 years old. Is suffering from tabes dorsalis and creeping paralysis, and is blind in both eyes. Deafness of the right ear set in four days previous to his coming to my notice.

(*e*) *In consequence of severe menorrhagia in child-bed, resp. after abortion*, in—

Servant woman, 49 years old. Can only hear a loud voice close to the auricles. Affection consecutive to abortion two years ago. Very severe noise and ringing in the ears.

(*f*) *In consequence of affections of the uterus*, in—

(1) Tailor's wife, 46 years old. Right ear hears whispering close to the auricle. Left ear hears only a loud voice close to the auricle. Severe noise and ringing. Prolapse of the womb.

(2) Carpenter's widow, 56 years old. Deafness of the right ear. Retroflexion of the uterus. Very nervous.

(3) Smith's wife, 43 years old. Hears a medium loud voice close to the auricles. Utmost hysteria. Suffered from prolapse of the womb for about 15 years. Has hallucinations of hearing.

(4) Merchant's widow, 51 years old. Hears whispering with the right ear at 5 feet, and with the left at 2 feet distance. Utmost hysteria, and suffering from retroflexion of the uterus. Is complaining of noises of the most various nature.

(*g*) *In consequence of saturnism*, in—

H. C., laborer, 57 years old. Hears whispering close by with both ears. Is working in lead dies. Was suffering from paralysis saturnina some weeks ago. There is still lead line in his gums.

The prolonged use of iodide of potassium resulted in perfect recovery.

(*h*) *In consequence of aneurysma of aorta Casilaris*, in—

G. R., laborer, 31 years old. Is complaining of a sense of a continual beating in the occiput, and of noise, like a waterfall, in his right ear. Can only hear a medium loud voice close to the auricle. Besides, there is difficulty of deglutition, and sometimes of respiration, especially during the night, when he often awakes with a feeling of suffocation.

The patient is in very poor health; his balance is unsteady, and he is laboring under great uneasiness and excitement. Mental faculties are not disturbed. Examination of the ears gave a negative result.

(*i*) *In consequence of mental emotions*, in—

C. B., tailor's wife, 39 years old. Is complaining of very severe noises, and impairment of hearing in both ears. There is no other cause than the prolonged mental emotions suffered in the last two years. Before this time the patient enjoyed good hearing.

Present State.—Right ear hears whispering close by; left ear at 5 feet distance. Tuning fork is heard in both ears. Passage for the air douche is good. Tympanic membrane is normal and the general health good. No hereditary disposition.

A trial of potassium bromate gave no result.

(*k*) *In consequence of using quinine*, in—

(1) H. A., railroad officer, 60 years old. Is suffering from impairment of hearing and severe subjective noises in both ears, consecutive to the ingestion of large doses of quinine against intermittent fever. He hears, with the right ear, whispering at 3 feet distance, and with the left ear at 4 feet distance. Tuning fork is heard in both ears. Passage for air douche is normal. The affection dates for about a year.

Iron preparations had no effect; subcutaneous injections of strychnia produced but little improvement.

(2) O. W., laborer, 21 years old, has suffered for about six weeks from ringing in his right ear, consecutive to the use of quinine against intermittent fever.

Right ear hears whispering at 2 feet, the left ear at 24 feet distance.

The use of bromhydric acid in doses of fifteen drops, in a little water, every fifteen minutes, resulted in perfect recovery.

4. *Sudden deafness without any assignable cause* was observed in the following case:—

F. R., merchant's widow, 53 years old, a nervous and hysteric woman, came under my notice August 11th, 1876, complaining of having suddenly lost the hearing of her right ear a day before. There is no assignable cause of the deafness. Menses had stopped five years ago. The power of hearing in both ears was always good.

Examination showed—

Right ear absolutely deaf; gives free passage for the air douche. All parts of the ear are normal. Left ear hears whispering at 20 feet distance.

Treatment with cathartics and with heurteloups on the mastoid process had no effect whatever.

5. *Deaf-muteism* was observed in the following cases:—

(1) B. F., saloon keeper's son, 4 years old, a well developed boy, had suffered, when 18 months old, from brain disease, in consequence of which he became deaf in both ears, and lost the faculty he had of speaking. Both tympanic membranes were opaque and concave. Not the loudest sound could be heard.

(2) S. B., boarding-house keeper's son, 13 years old, a healthy and good looking boy, had suffered, when 9 months old, from scarlatina, and was, from that time, a deaf-mute. Both tympanic membranes are opaque and flat.

(3) F. G., merchant's daughter, 22 months old, first born child, well developed and healthy looking and of healthy parents. No consanguinity between the parents, no hereditary tendency and no syphilitic history. The ears are normal. Deafness is congenital and absolute in both ears.

Periscope.

The Prevention of Relapses in Typhoid Fever.

The *Medical Times and Gazette* quotes, on this subject, a contribution which is of great practical importance, by Dr. H. Immermann, of Basle (*Correspondenz Blatt für schweiz. Aerzte*, October, 1878), in which he shows that we are, to a certain extent, able to prevent these by the internal administration of salicylate of soda. His observations were made in the Basle Hospital, into whose wards about 1200 cases of typhoid fever have been admitted from 1872 to 1877. Of these, from 12 to 19 per cent. relapsed —curiously enough, nearly double as many as under the old system of treatment, before cold baths were introduced systematically. The relapses could not have been due to errors in diet, as attention has been paid to this point during convalescence for many years. They could not have been caused by a reinfection in the hospital, for in 1877, out of a total of 4000 in-patients of all kinds, only eleven caught fever in the Hospital, whereas in 265 convalescents from typhoid, there were fifty-nine relapses. Hence it seems probable that the relapses must be traced to the action of a residuum of typhoid poison in the bowel of the patients themselves, by which, after a time, they become reinfected. If this theory be correct, the obvious inference is, as Immermann says, that we should systematically disinfect the body of a typhoid convalescent. Following out this reasoning, Immermann treated twenty-two such convalescents with four to six grammes of salicylate of soda for ten or twelve days from the first day of normal temperature. Of these patients, only one relapsed on the seventh day of the apyretic period, owing to neglect of attention to diet. In 1878, twenty-nine other male and female patients were similarly treated, and only one, which had begun the salicylate four days too late, relapsed; whereas of sixty-seven other convalescents who took no salicylate, fifteen relapsed. It was also found that many more relapses occurred under simple hydropathic treatment than when cold baths were combined with quinine or salicylic acid, the numbers being 20.3 and 15.8 per cent. respectively. These facts tend to prove that not only convalescents from typhoid fever, but also healthy persons exposed to the contagion of typhoid, should be treated with salicylate of soda.

Contagious Insanity.

In an article in the *Annales Medico-Psychologiques*, by Drs. Lasegue and Falret, the authors, after detailing several cases in which insanity was evidently the result of long and close association with the insane, arrive at the following conclusions:—

1. Under ordinary circumstances insanity is not contagious, and it is rare, even among the insane, for a delusion to be communicated from one individual to another.

2. Insanity only becomes contagious under exceptional circumstances.

3. These special conditions are—

(*a*) In the "Folie à deux," one of the two individuals is the active, the other the passive element. The former is the more intelligent of the two, creates the delusions, and imparts them to the latter, who receives them but slowly, and generally, after altering them to some extent. In time they agree on all points, and tell exactly the same story.

(*b*) To arrive at this condition the individuals must have lived long together, must have led the same lives, shared the same hopes and fears, and have been free from all external influences.

4. All the cases observed have presented nearly identical symptoms, and have only become developed under circumstances such as those described.

5. This variety of insanity is more common among women than among men.

6. The patients may be related, but frequently are not.

7. The chief point in the treatment is the separation of the patients from each other.

8. The second individual recovers first.

9. Very rarely delusions have been communicated by one person to several in his neighborhood.

Employment of Iodine in Coryza.

Dr. John M. Shaller writes to the Cincinnati *Medical News*—

Iodine inhalations may be used in all stages of coryza; and if thought absolutely necessary, internal medication may also be used. In the four cases iodine was used alone; began treatment on the first and second day of the trouble, in the following manner: half an ounce of the tincture was placed in a one-ounce vial and held in the hand, placed under the nose, with the mouth closed, ten or twelve inhalations being made; there was then a rest of two or three minutes and ten or twelve inhalations again were made, continuing in this way from fifteen minutes to one hour; fifteen minutes three times a day, or one hour once a day, as it seems to agree with the patient. The heat of the hand is sufficient to volatilize the iodine.

In two cases the trouble cleared up the day treatment began, after one hour's inhaling. In the other two, severe symptoms of headache, sneezing, and the acid mucus, were checked, with the clearing up of the coryza, with the exception of a very slight burning in the throat the next day. The headache is what worried them the most, which was relieved in a very short time. In the case of chronic catarrh, of over two years' standing, with headache almost constantly, it was relieved after two days' inhalations of fifteen minutes each, three times a day.

That it relieves this apparently trivial but annoying complaint in a short time, with a simple means, is worth the trial of every physician, and I would like to hear more from it. It produces its effects, probably, by depleting the mucous membrane, causing a slight watery discharge; neutralizing the acid mucus, preventing it from excoriating the upper lip, which is so often seen.

There is nothing original in the use of this remedy. That coryza will get well of itself in a week or so, in a great number of cases, is an excuse often used; and in the chronic cases, because they are stubborn, we do not like to trouble with them, and consequently, they must fall into the hands of quacks, who reap a rich harvest.

Medical Properties of Boldo.

In *New Remedies* we find the following:—

The remedial properties of boldo are mainly due to its oil and to a lesser extent to boldine, which exists in the leaves, according to the aforenamed authorities, in the proportion of only one part per 1000. Boldine is but slightly soluble in water, which it renders alkaline and bitter. It is soluble in alcohol, ether, and chloroform.

Boldo acts as a stimulant to digestion, and exerts a marked influence on the liver; this property residing in both the leaves and young stems. It is said that the first knowledge of its virtues was obtained through its action on a flock of sheep suffering from a disease of the liver, and which had been shut up in an inclosure in which the gaps had recently been repaired with boldo twigs. The sheep ate the twigs and leaves and are said to have recovered their health very rapidly, after passing large quantities of the "fluke worm," or gourd worm (*Distoma hepaticum* L.), a parasite which sometimes infests the biliary ducts of the sheep and produces the so-called liver disease.

Dujardin-Beaumetz made a series of experiments with the drug, with success in cases of atony of various organs when quinia was not tolerated by the patient, but care appears to be necessary in its use, as large doses produce vomiting. It does not seem to have much favor in European practice, whereas in South America its various preparations are prescribed as digestives, carminatives, tonics, and diaphoretics. In the form of a powder the leaves are used as a snuff.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——The address on State Medicine, delivered by Dr. Stanford E. Chaillé, at the meeting of the Louisiana State Medical Society, is an excellent paper, to which we shall have occasion to refer again.

——The fourth part of Klein's Atlas of Histology deals with cartilage and bone. It is, as usually, beautifully colored and most instructive. For sale by J. B. Lippincott & Co.

——A fifth edition of the "Formula book of Gelatine-coated pills and granules, fluid extracts," etc., has been published by the well-known firm of McKesson & Robbins, New York. It will be found quite convenient by the many physicians who use the preparations of that enterprising house.

——Dr. J. A. McArthur favors us with a copy of his pamphlet on "Consumption and its Treatment with the Hypophosphites;" it is a commercial essay, not designed to indicate the real position of these agents in the materia medica, but to collate all that has been said in their favor. Dr. McArthur manufactures a good article of hypophosphites, we believe.

——"Electricity, as Related to Medicine and Surgery," is the title of a collection of seven lectures, which appeard in the Virginia *Medical Monthly*, by Dr. A. D. Rockwell. They are reprinted by Wm. Wood & Co., New York (pp. 95, cloth, 8vo). They are directed to the general practitioner, and aim to give in brief compass a general survey of the theory and practice of electro-therapeutics. Of course, they are by no means a complete exposition of that difficult specialty.

——A circular has reached us, headed "Disinterested Testimony concerning Santa Barbara and Southern California." If it had been headed, "Collection of Laudatory Testimony," etc., it

would have been a more correct heading. Not a single criticism is inserted; yet Dr. R. M. Townsend, in the REPORTER, and many other very competent observers, have by no means a high opinion of Santa Barbara as a resort for consumptives. Such an authority as Dr. A. L. Loomis, of New York, says of it, "It has a bad record." When will there be some truth speaking about health resorts?

——The Superintendent of the Census for 1880 has sent a little book to each practicing physician and surgeon in the United States, where name and address are known to the Census Office, with the request that he will keep therein a record of all deaths occurring within his practice during the year June 1, 1879, to May 31, 1880, and will return the register, at the close of the year, to the Census Office. It is hoped that this effort to improve the vital statistics of the United States will meet with the aid of every physician, as in this respect we are sadly behind every other nation of equal civilization.

——The second number of the "American Health Primers," issued by Messrs. Lindsay & Blakiston, of this city (fifty cents each, in cloth), is entitled "Long Life, and How to Reach it," by Dr. Joseph G. Richardson. We might make some objections to the title, which is perhaps a little *ad captandum* for a work which is simply one on the general principles of hygiene, and also to the wearisome repetition of the "how" in the chapter headings; but in view of the generally excellent character of the contents, such small slips may be overlooked. The writer is an extremist in alcohol and tobacco, as well as in several of the theories he enunciates on medical questions. But it is by many believed that the merely probable positions of science are not potent among the multitude unless they are expressed in positive language; and perhaps Dr. Richardson is of this way of thinking. At any rate, the errors, if any, which his readers may be led into, will be on the safe side.

——Parts I and II of "Photographic Illustrations of Skin Diseases," by Dr. George Henry Fox, Professor of Dermatology, Starling Medical College, Ohio, have appeared. The photographs have been carefully taken from cases at Bellevue Hospital, and faithfully colored by hand by Dr. J. Gærtner. The photographs in the numbers before us embrace comedo, acne, lepra, keloid rosacea, etc. They are strikingly life-like, and deserve the highest praise. The text of a few pages to each photograph is descriptive and clinical, including treatment. The work will be completed within one year from the publication of Part I, the succeeding parts being issued monthly. As a guarantee to subscribers that the work will be issued promptly and regularly, the publisher asserts that the entire list of negatives composing the series are now in his possession; also, a large portion of the author's manuscript. The work will be complete in twelve monthly parts, each part consisting of four plates printed from the original photographic negatives, by a new and indelible process, on the finest quality of heavy card board, 10x12 inches, colored by hand, giving in each case the characteristic and life-like effects of the disease. Two pages of text in detail, will accompany each plate. This work will be sold only by duly authorized canvassing agents. No subscriber's name will be taken for less than the entire work. Price, per part, $2.

——Diphthonia paralytica is a rare disease, and Dr. E. C. Morgan has done well to report a case in a reprint from the *National Medical Review*. A young man of 19 years was nearly aphonic from prolonged laryngeal catarrh, which induced the disease named. Regarding the chronic laryngeal catarrh as being the cause of the paresis, and diphthonia a symptom of this paresis, Dr. Morgan's treatment was directed to the removal of catarrh, and then to the paresis by the use of intra-and extra-laryngeal faradization, and the administration of excito-motor stimulants. During the entire course of treatment, abstinence from alcoholic liquors and tobacco, and absolute rest of the voice, was recommended. In five weeks he had the catarrh nearly entirely relieved, the voice meantime having become much more distinct. He used as a local application to the larynx, zinc chloride, 0.75 gm. in 32.00 of water, and as an inhalation, alum, 15.00; aq. extract of opium, 0.20; glycerine, 50.00; rose water, 250.00. Both formulæ were made daily use of, until he began faradization, which was two months from the commencement of the treatment. Relief promptly followed the electrical medication, combined with strychnia.

BOOK NOTICES.

A Clinical Treatise on Diseases of the Liver. By Dr. F. T. Frerichs. Vol. III. New York, Wm. Wood & Co.

This is the last volume of Frerich's work, which we have heretofore noticed as issuing as one of the works of Wood's Standard Library. It contains an appendix of cases, and a moderately full index of the three volumes.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Half-Yearly Compendium of Med. Science,	**2.50**
Reporter and Compendium, - - - -	**7.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**8.25**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE GENUS QUACK.

They have in England a Medical Defence Association, the object of which is to surround the legitimate practice of medicine with those safeguards which will protect it and the public, to secure the operation of medical laws, and to suppress quackery. At its last meeting, in March, Dr. BENJAMIN W. RICHARDSON, the President of the Association, read an address on "The Phases of Quackery," in which he classified and ticketed, with the skill of a naturalist, the various species of the genus *quack*, those parasitic growths which fasten themselves on the ignorant and deluded portions of the public, and thrive on its ill health.

First, he spoke of the "terrorist quacks," who make their money by alarming their patient and magnifying his real or fancied ailment. These men do an incalculable amount of evil. They not only directly rob, they corrupt their victims. Seizing upon minor failings of a physical or moral kind, they distort or caricature such failings until their victim is literally distraught with the idea of the life-long misery that is in store for him. Moreover, having raised this misery, they do no mortal thing to allay it. It is a part of their shameless policy to keep the mental wound open, to offer temporary relief at the most, and to maintain silence at the cost of a levying which knows no end so long as the fears of the victim hold ascendancy over the acts of his life.

Next comes the "homicidal quack." He usually practices exclusively on the female sex, and generally is supported and aided by accomplices of that sex. His trade is to prevent conception and to produce abortion. His trade is a dangerous one, as it is distinctly criminal, and he is exposed to the risk of imprisonment. But his profits are large, and his patients are often of the class who are able and willing to pay well, and as averse as himself to the publicity of the Quarter Sessions.

A third order is the "nostrum-mongering quacks." These are not, perhaps, intentionally criminal, but they, nevertheless, take upon themselves duties and functions that are altogether foreign to their knowledge and skill. It is not so much that they practice irregularly, as that they pretend to treat diseases with the names of which they are not correctly familiar, and with the nature of which they have no conversance whatsoever. Some of these quacks take one particular disease or one particular set of organs of the body under their pretended care; others assume to treat diseases in general, in which case they commonly pretend to possess a particular kind of remedy which adapts itself to every kind of case. These last-named, owing to the method they pursue, attain, by the rule of chances, a certain measure of success. Vending some one active medicinal substance, such as opium, quinine, or iodide of potassium, and supplying the remedy to a great number of persons indiscriminately, they are sure to give it every now and then to a person who will be benefited by it, and so in time they get together a list of successful cases, or, as they call them, cures.

The "specialist quacks" are a species, the representatives of which carry out what they are

pleased to call a new system, or a distinct system of medicine. Some of these call themselves Botanic practitioners or Herbalists, or Thompsonians, or Electricians, or Indian Doctors, or Natural Bone Setters. These practitioners are very numerous; they exist in every large town. In their practice there is nothing diagnostic, neither is there any scientific art or skill of a therapeutical character. At the same time they often hold in their hands drugs of a most potent kind, which they use boldly, and often with the production of extreme effects on the body. Lobelia is one of their prime agents, and digitalis is another, and by the application of such active medicines they sometimes inflict a fatal result.

Druggists who are "counter prescribers" form another class which meets Dr. RICHARDSON's condemnation.

It would be quite possible for him to have extended this list, at any rate, if he had drawn on the genus as it is found in this country. Thus we have the "healing medium," who pretends to cure by inspiration, the "natural doctor," who heals by his presence and the laying on of hands; the mechanical quack, who has some machine which removes all disorders, and the like. But this classification of a noisome genus of pests to society probably became tiresome and disgusting to the writer.

NOTES AND COMMENTS.

The Use of the Forceps.

Regarding expectancy, ergot, the lever and uterine compression as the alternatives of the forceps, the Obstetrical Society of London recently stated the following general propositions for consideration:—

1. In lingering labor, when the head is arrested in the pelvic cavity, the forceps will almost always be better than its alternatives. 2. In lingering labor, when the head is engaged in the pelvic brim, and where it is known that the pelvis is well formed and the head normal, the forceps will be generally better than its alternatives. 3. In lingering labor, where the head is resting on the pelvic brim, the liquor amnii discharged, and it is known that there is no disproportion, or only a minor degree of disproportion, even although the cervix uteri is not fully dilated, the forceps will generally be better than its alternatives. 4. In proportion as the head is high in the pelvis, in the brim, or above the brim, the necessity, the utility, and the safety of the forceps become less frequent. 5. As a corollary under the conditions of the preceding proposition, increasing caution is called for in determining on the use of the forceps, and greater skill in carrying out the operation.

The Use of Iodine in Dry Asthma.

In cases of dry asthma, of constitutional character, without obvious exciting cause, Dr. C. A. L. Reed, of St. Louis, recommends, in the *Clinical Record*, the following prescription:—

℞. Liquor iodinii comp., f. ʒ j
Mel., f. ʒ ij. M.

SIG.—Teaspoonful every three hours.

He finds that the use of this is promptly (after the third dose) followed by a restoration of the secretion, diminution in the frequency and severity of the paroxysms from the start, an improvement in the appetite, an increase in the tone and vigor of the general system, and a perceptible increase in the volume of the urine, without any change in its specific gravity.

The Administration of Gelsemium.

According to Prof. Massini, the cases in which gelsemium produces most benefit are those of simple rheumatic neuralgia of the alveolar branches of the trigeminus; in those it rarely fails. It also sometimes relieves the pain remaining after the stopping of a carious tooth. Where there is any inflammatory affection of the bone or periosteum no good can be expected from the remedy. The medicine may, if necessary, be repeated several days in succession, the active principle rapidly passing off by the kidneys.

Non-tolerance of Chloral by Habit.

A noteworthy fact pointed out by Dr. J. B. Mattison, of Brooklyn, in his study of chloral inebriety, is that chloral habitués are exposed to a special danger. While the habitual use of opium admits of its gradual increase without risk, so that enormous doses can be taken with impunity, that of chloral is sometimes the reverse, and serious effects have followed the use of a smaller dose than the patient had for some time been accustomed to taking.

Chronic Contusion of the Heel.

Prof. Desprès, in his *Clinique Chirurgicale*, mentions this lesion as occurring in persons who are required to keep the upright position for a considerable time. The examination of the heel reveals nothing particular—there is no swelling or redness; pressure is not painful; but there is sharp pain if we press with the tip of the finger upon the inferior face of the posterior tuberosity of the os calcis, being the precise place at which that osseous point bears upon the sole during the upright position. The patient describes his sensation as one of heat—even of burning.

Those with arched or small feet and delicate skin, and who sweat copiously, are most exposed to this affection. Another predisposing cause is the wearing of shoes of thin leather, and prolonged walks upon bad pavements.

The treatment consists of rest and the application of a metallic sole, moulded to the foot and worn inside the shoe.

Galvanism in the Vomiting of Pregnancy.

A writer in the *Obstetric Gazette* says—

Dr. Fred D. Lenté, of New York, was among the first to speak of the utility of electricity in controlling the vomiting of pregnancy, as well as that from uterine irritation in the non-gravid state. He says that since the institution of this treatment he has never found it necessary to resort to uterine applications. Prof. T. G. Thomas has also spoken in the highest terms of its efficacy for nausea and vomiting in general, and for the obstinate gastric disturbance following ovariotomy. The method consists of the application of a broad, flat electrode over the epigastrium, and a similar one on the spine opposite, with the passage of a feeble, smooth, barely perceptible, induced current, prolonged for 15-30 minutes.

Prognosis in Fractures of the Skull.

Dr. N. P. Dandridge gives, in the *American Practitioner*, several cases of this injury, concluding with the following observation:—

The practical conclusion to be derived from the above cases is apparent: If, some time after (probably not more than some hours) an injury to the head, coma and hemiplegia develop themselves, and no fever is present, you may fairly infer that compression is being produced by a slowly forming hemorrhage, external to the membranes; and in this case the trephine offers prospects for relief. If, however, with coma and hemiplegia, there is a high temperature, and especially if these conditions develop some days after the accident, you may expect a diffuse arichnitis, and there is little or no hope from operation.

Poisoning by Alcohol.

Dr. De F. Willard, of this city, notes for us the following case:—

"I was called, at 9 A.M., to a boy 5 years of age, whose drunken father two hours before had, for some slight indisposition, forced him to take nearly two-thirds of a tumblerful of whisky. I found the patient insensible, the pupils contracted and non-responsive to light, respiration stertorous, but irregular, pulse slow and labored, extremities cold, conjunctiva injected—in about a condition of absolute coma. From this state he never roused, in spite of hot and cold baths, diffusible stimulants, emetics, etc., but died at 6 P. M., eleven hours after taking the draught. No post-mortem."

Correspondence.

FOREIGN.

Letter from London.

Ed. Med. and Surg. Reporter:—

To many of your readers it may be of interest to hear some of the particulars of the London hospitals, when founded, and the character and extent of their work. The Middlesex Hospital was instituted August, 1745, for sick and lame patients; and in 1747 a ward was opened for the reception of lying-in married women.

The hospital consisted, at first, of a building in Windmill street, but this being found incommodious and inadequate, a new and commodious hospital was built on a convenient site in the "Mary-le-Bone Fields," as they were then called. Toward the close of the past century causes not now very distinctly known interrupted the favorable progress of the Middlesex Hospital; many annual Governors discontinued their subscriptions, the hospital became involved in debt, and most of the wards were shut up.

The Revolution in France drove to England a number of emigrants, and of these, many were French clergymen, in a state of utter destitution. The western wing of the hospital was made a receptacle for a large body of these sick French emigrants.

The late Lord Robert Seymour has the merit of having retrieved the establishment from almost complete ruin, interesting himself in its behalf, prevailing upon many of the nobility, as well as King George IV, to join in the good cause. This same Lord Seymour had a concert given at the King's Theatre, in 1808, which yielded the splendid sum of £2498 2s, and thus the hospital got rid of a large accumulation of debt. In 1848 extensive and costly improve-

ments were made, correcting deficiencies in ventilation, etc. From this time the prevalence of erysipelas rapidly diminished: previous to this, this and kindred diseases were very common. The hospital now contains 310 beds. The average annual attendance of interne patients is 2000; of out-patients 20.000. There is a chaplain, a member of the Established Church of England, connected with the institution; patients are allowed, however, to have their own spiritual advisers. An amateur dramatic performance in aid of the funds of the Cancer Department yielded, in May last, £195.

As a matter of reference to those whom it may concern or interest, the following is submitted:—Every subscriber of three guineas becomes a governor of this hospital, so long as such subscription shall be continued; thirty guineas makes a life governer; ten guineas annually entitles one to one patient in the hospital at all times. Every lady, being a governor, may vote at all elections by proxy, provided that such proxy specify her place of abode, and the name of the candidate for whom her vote is given.

Among the vice presidents is Sir Thomas Watson.

There is a special cancer department connected with this hospital, and it provides that three wards are to be kept open for the admission of, at least, thirty females, and the male patients afflicted with cancer. Also, that out-patients afflicted with cancer be specially attended and relieved, with advice and medicine, and that all cancer patients be admitted without letter of recommendation; also, that all persons afflicted with cancerous diseases requiring operation, or persons afflicted with these diseases returning after operation, or persons with the same diseases in an acute stage, are to remain in the cancer wards until released by death or relieved by art, unless it shall be necessary to discharge them for ill behavior. Also, that changes of raiment be found such patients if it is found to be necessary. The patients treated in 1877 were as follows:—

Medical, with letters	439
do urgent cases	725
Surgical, with letters	157
do urgent cases	929
Out-patients, medical, with letters	5,590
do do urgent cases	2,838
do surgical, with letters	1,741
do do urgent cases	6,312
Diseases of women and children	2,184
Lying-in cases, attended at their own habitations	447
Dental	978
Skin	974
Ophthalmic	886
Ear and throat	337
Cancer	95
Total	24,632

Connected with the institution is a fund for (1) sending patients to Margate Sea-bathing Infirmary, and to the Walton Convalescent Institution, and (2) for the purchase of linen, etc.

In 1835 a Medical School was established in connection with the hospital, under the same management and control as the hospital.

The "Chief Dispenser" of the Middlesex Hospital, I found to be very polite; he kindly answered my many inquiries, and escorted me around the extensive drug departments. Mr. S. R. Chalice, for such is his name, said that the board was very liberal in the allowance of drugs and liquors. In many of our American dispensaries I know quinine is allowed to be dispensed only in very sparing quantities; here about 400 ounces a year are used. Good drugs, not fancy ones, are bought. The very best of quinine, morphia and cod-liver oil always are ordered. All their tinctures are made in the "Tincture Room," a spacious room, well supplied with all the requisites for making these alcoholic preparations. It is a standing rule that all preparations possible must be made in the house. Chemicals are bought, as being cheaper and better than could be produced by the institution. In the "Dispensing Room," all bottles containing poisons or preparations used in small doses are fluted; powerful poisons having a label "Poison," on the same kind of a bottle. Mr. Chalice says that during the many years that he has been there no accident has occurred in his department.

Like similar establishments, a "house pharmacopœia" is used. I saw nothing novel in it, or what would be of any particular interest to my readers. The "collyria" were the usual silver, lead and zinc mixtures. The "gargles," borax, alum and potash. Among the various enema was "enema vulgæ:"—

℞. Hordei decoc., Oj.

A pill much used being pil. capsici et opii.

℞. Capsici, grs.iij
Ext. opii, gr.ss.

One pill.

This Hospital is situated on Berner's street, off from High Holborn or Oxford, and just near it, on the same street, is St. Peter's Hospital; also the Pathological and the Obstetrical Societies of London. The average attendance at the Middlesex Medical School is 130.

It may not be generally known that the Guinea exists no longer, save as a specimen coin. West End shop keepers, dealers in pictures, old bronzes, jewelry, etc., are very fond of quoting guineas instead of pounds. Guineas are also generally quoted in sales of horses, and at auction sales, and as doctors' and other professional fees.

To be in time for the next mail, I must close at once, though I had hoped to reach the point of telling you of the interesting time I have had with J. Hughlings Jackson and Dr. B. W. Richardson. But of this anon. C. C. V.

DOMESTIC.

Letter from Cincinnati.

Ed. Med. and Surg. Reporter:—

A glance at the contributions to local medical literature from the medical men of this community will show that there is no lack of individ-

ual effort and studious pursuit on the part of the profession in this city. A few evenings since Dr. N. P. Dandridge read before the Cincinnati Medical Society a paper entitled, "A Case of Empyema following Gunshot Wound of the Chest, Successfully Treated by Drainage and Exsection of a Portion of Rib." The paper subsequently appeared in the *Lancet and Clinic*, together with the critical remarks it called forth from Drs. Kearney, Mackenzie and Judkins. Dr. S. C. Ayres has quite recently added another to the numerous "Contributions to Injuries of the Eye," which have brought his name so prominently to the attention of the profession in the special branch of practice—ophthalmic surgery—to which he is devoting attention. The same is true of another young practitioner of this city, who is rapidly earning a name and fame commensurate with the labor he is devoting to the special studies in which he has been so long engaged; I refer to Dr. A. T. Keyt, whose researches in connection with the sphygmograph and the pathology of the circulation are known to all who aim to keep up with the times in such matters. On some future occasion I shall take time to trace Dr. Keyt's researches in the practical application of mechanism to the demonstration of the movements of the circulatory organs in health and disease; his last is one of his most interesting papers, and is entitled, "The Sphygmographic Indications of Heart Disease."

What think the readers of the REPORTER of a case of talipes equinus induced by malarial poisoning? Of a patient presenting the phenomena attendant upon this form of club foot as one of the features of a paroxysm of fever and ague? Dr. W. H. De Witt, a well-known and highly esteemed practitioner of this city, publishes the details of a case in which a patient, previously of sound health, develops chills and fever, and in whom the daily chill is followed by talipes equinus, which continues during the reactive fever, headache, perspiration, etc. Quinine relieved the chills and cured the talipes after this curious phenomena had recurred daily for several weeks.

A very interesting paper on "Cancer of the Stomach," from the pen of Dr. John S. Cleveland, founded on cases under his own observation, recently appeared in the columns of the *Lancet and Clinic*. The pyloric orifice of the stomach of one of the cases alluded to was exhibited at the Academy of Medicine on the evening of April 21st, and gave rise to quite an animated discussion after the conclusion of Dr. Vance's paper. Dr. Cleveland's rules for the differential diagnosis between chronic ulcer and cancer were noteworthy, and should be borne in mind. Pain after eating, and on pressure, the nature of the materials vomited, the presence or absence of a tumor in the gastric region, the duration of the complaint, and the order in which the symptoms were evolved, were the points dwelt upon by the essayist.

On the evening of April 21st—the occasion when Dr. Cleveland presented his specimen of cancer of the stomach—Dr. Reuben A. Vance read a paper before the Academy of Medicine on "The Influence of Constipation in Developing Disease in the Rectum and Anus; An Inquiry into the Structure and Office of the Large Intestine and its Terminal Orifice, and the Manner in which they Behave when Diseased." The paper as read before the Academy was an extended development of the views Dr. Vance has at different times shadowed forth in his publications on the physiology of the large intestine and its terminal orifice, but more especially on the pathology of the rectum and anus. The Doctor drew attention to the similarity that exists between the œsophagus and the rectum—the commencement and termination of the alimentary canal; and declared that the resemblance was not limited to visual characters and anatomical appearance, but could be traced in the offices performed by the respective structures. For instance, when the canal of the œsophagus is not distended by a bolus of food, its walls are in apposition; notwithstanding the popular and professional preconception to the contrary, he declared that an identical state of facts existed in the rectum—that normally the walls of the rectum were in contact, and its canal closed, except during the few moments following a call to the water closet, and preceding the regular evacuation of the bowels; that coincident with the uneasy sensation which is recognized as the call to evacuate the bowels, the band of muscular fibres at the junction of the rectum and sigmoid flexure pass through this orifice and enter the canal of the rectum. As a general rule, this opening of the passage between the colon and rectum occurs but once in the twenty-four hours; if the intimation then given is heeded, and the individual retires, the bowels are easily and naturally evacuated. If, however, on the contrary, this call is resisted, the uneasy sensations, after persisting for a variable period of time, subside, an antiperistaltic contraction is excited in the walls of the rectum, and the fæces which have passed from the colon into the rectum are returned to the cavity of the sigmoid flexure, and the walls of the rectum again fall together. When the call to retire is responded to, and the fecal matter passed from the sigmoid flexure into the rectum has been voided, the remaining contents of the large intestine are slowly urged forward, from the cæcum, through the colon, to the sigmoid flexure, to be extruded in their turn. Consequently, when the call to defecate is properly responded to, and that physiological act thoroughly accomplished, the excrementitious matter in the sigmoid flexure and cæcum is voided; that part contained in the former cavity being the first to pass away, and that lodged in the latter slowly traversing the ascending transverse and descending colon, and making its exit through the rectum without stopping for any length of time at any point between the cæcum and anus. The fecal matter lodged in the large intestine prior to the call for defecation seems to be divided into two masses, and to rest in two distinct cavities; one portion in the cæcum, and the other in the sigmoid flexure; and while it is certain that normally none of the fæces distend the canal of the rectum, except at the time and under the circumstances noted, it is also quite probable that the ascending and transverse colon are equally free from its presence. Simple as these facts are, they are not so generally diffused as their importance demands.

So long as the physiological offices of the large intestine are but imperfectly known, it is useless to try to inculcate proper ideas relative to the hygiene of that organ. After concisely stating the behavior of these parts in health, Dr. Vance describes certain anatomical points of interest, and gives a full account of the mechanism by which constipation induces congestion of the lining membrane of the rectum, spasm of the anal sphincters, and finally, ulceration of that organ, and the attendant complications, fistulæ, hemorrhoids, abscesses, prolapsus and stricture.

One of the most interesting papers brought before the Academy for many a day is the one Professor Conner read, on the evening of May 5th. The title indicates its nature: "Cancer; Has it a Constitutional or Local Origin?" A moment's reflection will indicate the vast number of living, inquiring and intelligent individuals to whom this question is no bare abstraction, but a vital problem, instinct with all that makes life precious not only to persons, but to families. Think, Mr. Editor, of the number of your readers—medical men, those to whom this question comes with all its force, because to them the truth is unfolded and their eyes are not blinded by sophistry—whose hearts will beat the faster when these lines attract their attention, and who cannot hide from their own consciousness the sorrowful fact that in their own or in their wives' families this dread taint is somewhere hidden away, and that some day in the future it will creep out, either in themselves or in their descendants. There are so very few families to whom this question is not of vital moment, that one can truly say that Dr. Conner's paper touches a subject in which every fireside has an interest such as few topics can excite. It is utterly impossible for me to do justice to Dr. Conner's arguments in the space at my disposal, still I will try and give your readers an outline of what he said. Commencing with a terse version of the meanings ascribed to the terms "constitutional" and "local," he quoted Dr. Moxon's statement of the question, "Does the first cancer that appears in the patient's body generate the cancers which appear afterward? Does it precede them in every way? Or, on the other hand, is there a general state of the whole system which is ready to put out cancer anywhere, and puts out the first in the same way as it afterward puts out the second and the third?" Truly, says Conner, an affirmative answer to the first question places cancer among the local diseases; to the second, among the constitutional affections. Rapidly reviewing the grounds upon which the constitutionalists base their belief, he summarizes them as, "1st, heredity; 2d, multiplicity; 3d, diversity; and 4th, depravity." In other words, that the disease runs in certain families; manifests itself in tumors of varying number; located in histologically different organs and tissues; and is attended by a progressive breaking down of health and strength, terminating only in death. After carefully weighing the arguments founded on these points, especially those based on recurrence, he says: "Taking into consideration the fact that the disease cells can be readily transmitted through the lymphatics and blood vessels, and can, by their own inherent motility, pass into and through the various tissues, the clinical history of a case of cancer is perfectly intelligible on the theory of local origin. If the growths, primary and secondary, were, so to speak, only symptoms of the disease, instead of the disease itself, why should there be so constantly observed an exact correspondence between the special characters of the original and subsequent tumors? On the theory of local origin, the principle that like begets like, there is nothing strange in the fact that an epithelioma is followed by an epithelioma, no matter where located, or an osteoid cancer by a bony growth in a muscle, nor that the hepatic nodule following primary cancer of the rectum shows microscopically the cellular structure of the lower bowel. If the primary growth is but an evidence of preëxisting diathesis, how does it happen that while such diathesis is so strongly inclined to throw out its manifestations in one of two twin symmetrical organs, the breasts, it comparatively seldom appears as a secondary growth in the other? It is not because the primary growth has exhausted the cancer-producing element in the constitution, for there is no scarcity of secondary tumors at different points. It is not because of less-advanced degeneracy of the second breast, for it is, if anything, more wasted than the first was when attacked. Who can explain it on the constitutional hypothesis? On the local theory, Dr. Conner holds the explanation simple and near at hand. It is much easier for the cells to travel in other directions, and they are much more likely to do so. But, say the constitutionalists, "that there is and must be an organic something antecedent to and necessary to the development of the primary tumor, is shown by the fact that a given exciting cause operating similarly upon a number of persons, in one only will the cancer be produced. A hundred men smoke short clay pipes; one only has epithelioma of the lip; as many women receive a blow on the breast; in one only is the result other than temporary and insignificant. But may there not be here a taken-for-granted cause and effect relationship which is purely assumed; or if not so, does the irritation or the contusion act in so simple a manner as is often believed?" The lip, subjected to changes of temperature, becomes fissured; is it surprising that epithelial growth should once and awhile follow these fissures; that these epithelial cells should penetrate to the submucous connective tissue, there to remain until the mutations of tissue decay incident to advanced life stimulate it into development, and an epithelioma appear? Why exclude the same process at the nipple in breast cases? or to follow Dr. Conner in this class of cases, may not mammary carcinoma spring up in virtue of an arrest of the normal infolding or outfolding process, or of the acceleration of growth of an embryonic cell by the hyperæmia which results from an injury? Why should not wounds in cancerous individuals become open cancers in all cases, if the constitutionalists' theory is correct? But in truth, the origin, progress and result of cancer show that primarily it is not a constitutional disease; and to this conclusion the arguments advanced by Dr. Conner are among the most cogent yet ad-

duced by those who claim the local origin of this affection.

The discussion following Dr. Conner's paper, to which I am painfully conscious my outline does but scant justice, revealed a curious state of things. I can well remember when the advocates of a local origin were few and far between; here, in the Academy, we have Drs. Conner, Buckner, Ransohoff, Forcheimer, Davy and Orr, outspoken in their advocacy of a local origin of cancer, while but one or two gave a feeble assent to the "constitutional" doctrine. In fact, neither Drs. Cleveland, Reaney nor Walton should be ranked among those entertaining the latter belief, although they would doubtless object to being considered partisans of the local origin theory. CINCINNATI.

NEWS AND MISCELLANY.

New Hampshire State Medical Society.

The following are the officers of the New Hampshire State Medical Society, elected at the eighty-ninth annual meeting, held in this city June 17th and 18th:—

President, Thomas J. W. Pray, M.D., Dover.
Vice President, Granville P. Conn, M.D., Concord.
Secretary, Moses W. Russell, M.D., Concord.
Treasurer, Lyman B. How, M.D., Manchester.

The Metric System.

Dr. Edward Wigglesworth, of Boston, is warming up considerably on the metric system. He is beginning to abuse our people in good set terms about their hesitation in the matter. Hear the way he closes his last manifesto:—

"We need a benevolent despot who would compel the use of the Metric System here after a fixed day. After a week no one would have any more trouble; after a month people would wonder how they could ever have used anything else, the labor of learning is so slight, the gain immense.

"All the poor peasants of Europe, the lowest classes of 'effete despotisms,' etc., have been able to adopt it at once, and yet Americans, self-ruling, are really too lazy, while merely claiming to be too stupid so to do. Shame on a country which 'to party gives up what was meant for mankind.'"

Items.

—In the medical department of Yale College it is proposed to extend the period of study to three years, and an examination will be required for admission and advancement. The methods of instruction will be made less didactic.

—All the Southern cities are keeping close watch of their sanitary condition, and the reports from all quarters are decidedly encouraging. Not a single case of yellow fever has been anywhere discovered, and in many cases the death rate thus far this year is considerably below the average.

OBITUARY RESOLUTION.

Dr. F. F. Maury.

At a recent meeting of the Medical Board of the Philadelphia Hospital, held June 7th 1879, the death of Dr. F. F. Maury, one of the surgeons to the hospital, being announced, on motion the following minute was adopted:—

"*Resolved*, That the Medical Board has heard with deep regret of the death of their late colleague, Dr. F. F. Maury, for more than fourteen years one of the staff of this Hospital. That in his death the Board has lost one of its oldest, most active and useful members, the Hospital a distinguished, brilliant, and careful surgeon. A clinical teacher of rare ability, who had endeared himself to thousands of students by his eloquence, skill and energy, and the profession at large a member who had achieved in his comparatively short life a position and success but rarely attained."

QUERIES AND REPLIES.

Dr. J. H. S., of Pa.—Ringer's *Therapeutics* is highly esteemed by English writers.

Dr. J. J. B., of Texas.—"Is it not possible for gonorrhœa to bring about such nutritive changes in the female genitalia as to predispose to perineal laceration?"

Ans.—We can recall no cases in point; perhaps our readers can.

Dr. D. W. J., of N. B.—REPORTER and *Pocket Record* together will be sent for $6.25.

Dr. S. C. T., of Md.—Prof. Shiff recommends that choleate of sodium be given in half-gram doses twice daily. It may be conveniently prescribed in pill form coated with gelatine, or in gelatine capsules.

Dr. B. E., of N. Y.—The formula is an obvious error. The 5 was placed for the 3. But we presume no one would be led astray by such a patent oversight.

Dr. J. N. T., of N. Y.—Can you explain what is the cause of the peculiar rushing sound caused when one or both ears are tightly closed by the ends of the fingers. An article has been in the press which states that, according to Dr. Hammond, it is due to the noise of the circulation of the blood in the ends of the fingers.

That this is erroneous may easily be proven by the fact that the same phenomena will be observed if the ears are tightly or firmly closed with any other solid substance.

What, then, is the cause of this apparent sound?

Ans.—We suggest that it is not from the circulation of the blood in the fingers, but the hemmed and compressed blood current in the sides of the auditory canal.

MARRIAGES.

ROBINSON—BONNER.—At the residence of the bride's parents, in Fairfield, Texas, February 12th, 1879, by the Rev. T. J. Bonner, of Woodland, Texas, W. Brice Robinson, Esq., of Fairfield, and Miss Sallie Belle, eldest daughter of Dr. J. I. Bonner.

SMITH—SCUDDER.—On June 5th, by Rev. Joseph G. Symmes, assisted by Rev. Dr. S. T. Lowrie, Rev. George L. Smith, of Cedarville, N. J., and Sarah G., daughter of Jno W. Scudder, M.D., of Ewing, N. J.

TAYLOR—HUDSON.—On Wednesday, June 11th, at the Church of the Holy Trinity, by the Rev. Brady E. Backus, Dr. Thomas C. Taylor and Sadie J., daughter of I. N. Hudson, all of New York.

DOCTOR RABUTEAU'S

(Laureate of the Institute of France.)

DRAGEES, ELIXIR & SYRUP

Of Proto-Chloride of Iron.

"The experiments made in the hospitals of Paris have demonstrated that *Dr. Rabuteau's Dragees, Elixir and Syrup* regenerate the red globules of the blood with a rapidity never observed with the use of the other ferruginous preparations. These results have been proved by the various *Compt-Globules.*

"The ferruginous preparations of *Dr. Rabuteau* do not cause any constipation, and are perfectly tolerated by the weakest persons."—*Gazette des Hospitaux.*

Dr. Rabuteau's Elixir is prescribed when some difficulty is experienced in swallowing the Dragees; it is especially adapted to weak persons, whose digestive functions need strengthening or stimulating.

Dr. Rabuteau's Syrup is especially prepared for children, who take it readily, because of its agreeable taste.

MEYNET'S

DRAGEES OF COD-LIVER EXTRACT.

Careful experiments have established the fact that the **EXTRACT OF COD LIVERS** contains very valuable properties, which render it superior to the ordinary cod-liver oil. It is composed principally of *Gaduine*, large proportions of *Iodides, Chlorides, Bromides, Phosphoric Acid, Lime, Soda* and *Ammonia*, and especially *Propylamin*, all of which enter, but in very small proportions, into cod-liver oil.

These dragees of pure cod-liver extract take the place of cod-liver oil, and have been used with eminent success by medical celebrities of Europe in cases of *Scrofula, Rheumatic Affections, Rachitism, Phthisis*, and in all cases where a propylamic medication is indicated.

MEYNET'S DRAGEES are sold in bottles containing 100 dragees. Dose, 2 to 6 a day. Each dragee is equivalent to two tablespoonfuls of cod-liver oil.

MEYNET'S GRAINS are small granules intended for children. 10 are equivalent to 1 dragee.

E. FOUGERA & CO., New York, Agents for the U. S.

RIGOLLOT'S MUSTARD PAPER.

Is one of the most important and useful discoveries of the age, but it is not (as certain dealers of bad faith pretend) a preparation that any one can make, for it is not manufactured with a mustard that every one can buy.

RIGOLLOT'S MUSTARD PAPER.

Is the invention of Mr. P. RIGOLLOT, who is the exclusive owner; it is the only preparation which has been adopted by the civil and military hospitals and the armies and navies of France and England, and which has obtained a medal at the Centennial Exposition at Philadelphia. All other mustard plasters or leaves of whatever name, are but imitations of the original

RIGOLLOT'S MUSTARD PAPER.

Physicians will find it the most reliable sinapism, prompt and certain in its action, and will therefore always prescribe it. Every sheet in order to be genuine must bear the annexed signature of the inventor, *P. Rigollot*

Sold in tin boxes containing 10 sheets, also 25 and 100 sheets, by all respectable chemists throughout the world.

E. FOUGERA & CO., Agents,

NEW YORK.

PHOSPHOROLE.

PHOSPHORUS and COD-LIVER OIL

have now an established position throughout the civilized world as important therapeutical agents. A *perfect combination* of the two has long been a desideratum, since they are both of value in the same disorders, while the cases in which one is demanded and the other contra-indicated are exceedingly rare.

The combination in PHOSPHOROLE has the twofold advantage of furnishing *the best possible form* for the administration of *phosphorus*, and *a more effective form* for the administration of *cod-liver oil*.

With regard to the former, it has been decided by the highest chemical and medical authorities that *phosphorus* should be administered *in a free state*, and in a vehicle which ensures its *perfect diffusion*, its *absolute unalterability*, and, as far as possible, its *prompt assimilation* without the gastric irritation to which the ordinary methods of exhibiting the agent give rise. It is well known that pills, emulsions, solutions in ether, chloroform, vegetable oils and resin, etc., have all failed to fulfill one or more of these conditions. Even an ordinary solution of phosphorus in cod-liver oil would not answer the purpose in all respects. We claim, however, that PHOSPHOROLE completely satisfies all the conditions. From the method of preparing it, in an atmosphere of dry carbonic acid, the phosphorus is *entirely dissolved without oxidation*, and by our mode of manipulation *a positive uniformity of strength* is ensured. It is then promptly bottled and sealed, and its *stability and permanence* thus secured. The exact amount of phosphorus in each dose is known, its efficiency is ensured, and the irritant effects upon the stomach are reduced to a minimum by the blandness of the oil. As a means then of administering *phosphorus* in the many cases in which it is indicated as a *nervous tonic and stimulant*, it is claimed that PHOSPHOROLE is the best attainable in the present state of our knowledge.

The value of *cod-liver oil* in phthisis is so familiar to the physician that it is needless to dwell upon it. But the value of *phosphorus* is also universally recognized in this disease, especially when complicated with nervous derangements. The *combination* of the two therefore furnishes a more effective form for the administration of cod-liver oil in the great majority of cases in which that remedy is indicated, and one which will at once commend itself to the profession.

A dose of two teaspoonfuls of PHOSPHOROLE contains $\frac{1}{100}$ of a grain of phosphorus. This dose, when given after a meal, is effective, and not very liable to interfere with digestion. *Phosphorus is cumulative in its action, and should be administered with watchful care.* About $\frac{1}{12}$ grain is considered the largest safe dose, and we rarely need go higher than $\frac{1}{20}$ or $\frac{1}{30}$ of a grain. At the very first appearance of the smallest gastric derangement, the exhibition of phosphorus should be stopped.

PHOSPHOROLE is handsomely put up in pint bottles only, and may be obtained at all first-class druggists throughout the United States.

Descriptive Circulars furnished upon application.

PARIS EXPOSITION, 1878.

We take pleasure in stating that we were awarded a

SILVER MEDAL

FOR OUR EXHIBIT OF

SOLUBLE-COATED PILLS

AT THE

Universal Exposition, Paris, 1878.

This being the *only Silver Medal* (the HIGHEST RECOMPENSE awarded to Pills), is conclusive evidence as to the superior merits of our Soluble-Coated Pills, as compared with all other kinds and justifies the claims we have always made for the excellence of our manufactures.

WYETH'S

DIALYSED IRON.

(FERRUM DIALYSATUM.)

A Pure Neutral Solution of Peroxide of Iron in the Colloid Form. The Result of Endosmosis and Diffusion with Distilled Water.

PREPARED SOLELY BY

JOHN WYETH & BRO.,

PHILADELPHIA.

This article possesses great advantages over every other ferruginous preparation heretofore introduced, as it is a solution of iron in as nearly as possible the form in which it exists in the blood. It is a preparation of invariable strength and purity, obtained by a process of dialysation, the iron being separated from its combinations by endosmosis, according to the law of diffusion of liquids. It has no styptic taste, does not blacken the teeth, disturb the stomach, or constipate the bowels.

It affords, therefore, the *very best* mode of administering

IRON

in cases where the use of this remedy is indicated.

The advantages claimed for this form of Iron are due to the absence of free acid, which is dependent upon the perfect dialysation of the solution. The samples of German, French and American Liquor Ferri Oxidi Dialys. which we have examined give acid reaction to test paper. If the dialysation is continued sufficiently long, it should be tasteless and neutral.

Our dialysed Iron is not a saline compound, and is easily distinguished from Salts of Iron, by not giving rise to a blood-red color on the addition of an Alkaline Sulpho-Cyanide, or a blue precipitate with Ferro-Cyanide of Potassium. It does not become cloudy when boiled. When agitated with one part of Alcohol and two parts of Ether (fortior), the Ether layer is not made yellow.

Physicians and Apothecaries will appreciate how important is the fact that, as an antidote for Poisoning by Arsenic, Dialysed Iron is quite as efficient as the Hydrated Sesquioxide (hitherto the best remedy known in such cases), and has the great advantage of being always ready for immediate use. It will now doubtless be found in every drug store, to supply such an emergency.

Full directions accompany each bottle.

Physicians will find our DIALYSED IRON in all the leading drug stores in the United States and Canada.

It is put up in bottles retailing for **ONE DOLLAR**, containing sufficient for four months' treatment Large size is intended for hospitals and dispensing. Retail at $1.50. Price Lists, etc., sent on application.

PUERPERAL METRITIS.

Read before the Northern Medical Society,

BY E. E. MONTGOMERY,

Of Philadelphia.

Gentlemen:—I believe I cannot better introduce this subject than by reading you the notes of a case.

May 5th, 1878, at the Philadelphia Hospital, Lilian M., aged 24, single, primipara, after a labor of twelve hours, was delivered of a female child. The resident, Dr. J. W. O'Neill, removed the child and attempted to deliver the placenta by pressure over the abdomen and simultaneous traction upon the cord, but found it adherent. An hour having elapsed during these efforts, he introduced his hand into the uterus and with difficulty dissected it off.

6th. Temperature 100°, pulse 84; general appearance good. Uterus tender, enlarged, extending an inch above the umbilicus, lochia profuse, but normal in appearance.

7th. Temperature 102°. Pain and tenderness more marked. Was given 30 grs. quinine in the evening.

8th. I saw this patient for the first time, and found the skin hot, pulse frequent, complaining of feeling weak, restless, tongue furred, countenance anxious. An examination of the abdomen disclosed a well marked tumor (the uterus) occupying the hypogastric region, and extending to the umbilicus, tender to pressure. On the left side of the uterus a small tumor, the size of a walnut, protruded the skin, and was very sensitive to the slightest touch. Lochia free, slightly offensive. Leeches were ordered over the abdomen, to be followed by flaxseed poultices, a nourishing diet and stimulants.

℞. Ext. ergot fl.,
Tr. nucis vom.,
Tr. ferri chlor.,
Tr. cinnamom., āā f.℥ ss. M.

Sig.—℥ j ter die. Opium by suppository or pill, q.s. to relieve pain.

9th. Pain and distress much less; pressure over the abdomen borne with but little complaint; tumor on the left almost disappeared.

10th. No pain, and but slight tenderness; lochia decreased, very offensive; stools frequent; was given a chalk mixture, and vaginal injections of a solution of carbolic acid ordered—the tube to be introduced once daily, with a flexible catheter attached, into the uterus, and the cavity washed out. For this purpose a douche was used in place of the syringe. During the next few days her condition was very much improved, countenance brighter, expressing herself as sanguine of getting well; diarrhœa checked, appetite improved, able to sit up to her meals; lochia slight, offensive odor lost. The uterus, which had remained enlarged, began to decrease after the first intra-uterine injection, until by the 25th it could not be felt above the pubes. She did not, however, gain much strength. The temperature and pulse remained higher than normal, with a marked evening exacerbation. We gave tr. ferri chlor., gtt. v every two hours, with a large dose of quinine at night. All the symptoms improved so much that we regarded our patient out of danger, when suddenly, June 9th, she became much worse. Prostration was marked, weak, vomiting and purging, the surface bathed with a cold, clammy sweat, emaciation

rapid, countenance pinched and anxious, unable to retain any nourishment. She died on the 12th.

Autopsy.—Body much emaciated. Thoracic organs presented nothing abnormal—no evidence of peritonitis, excepting a few ounces of effusion. Uterus—the fundus had completely sloughed off, and the cavity was dilated large enough to hold an ordinary egg, ending above in a thin ulcerated edge. The whole uterus resembled very closely a funnel. The cervix, and lower portion of the body were in a comparatively normal condition, for the puerperal state.

Metritis affects the parenchyma or muscular structure of the organ, and as it is generally associated with endometritis, some pathologists have considered the latter as the primary lesion, but this is doubtful. It is a frequent lesion in some epidemics of puerperal fever, while in others it is absent. We have also reason to believe it to be the primary lesion in many cases of local peritonitis, cystitis and suppurative inflammations of the pelvic tissues.

In the case noted above you will remember the excessive size of the uterus. In physiological convalescence the uterus disappears behind the pubes from the sixth to the tenth day; at the earlier period in primipara; hence, if at the ninth or tenth day we find the uterus still three or four inches above the pubes, we are justified in being anxious for our patient.

Before entering upon the consideration of the pathology, it will be well to spend a few minutes in the study of the physiological changes the organ undergoes after delivery.

M. Colin says, "a few hours after delivery the interior of the uterus is covered with clots of blood, which, when removed, show a soft, moist, reddish layer lining the internal surface, excepting where the placenta was attached. This layer increasing in thickness near the fundus, of a reddish-gray color, very friable, covers the muscular tissue, and has been in process of regeneration since the fourth month of gestation. It terminates at the upper boundary of the cervical canal, in an irregular edge. The membrane is firm, torn with difficulty, covered with a slightly reddish mucus, and does not undergo exfoliation, like that of the body. After the ninth day epithelial cells are found in the uterine mucous membrane, and are followed by granules, nuclei, glandules, and minute capillary vessels. By the twentieth to the thirtieth day it has acquired sufficient firmness to resist the action of a stream of water, but can be completely scraped off by the handle of a scalpel."

The site of the placenta presents a greatly different appearance. It, before delivery, measures six to eight inches, is afterward reduced to three or four, and this decrease is constantly progressing.

According to M. Robin, the form of the seat also changes; at first being nearly circular it now becomes oval, with irregular, sinuous, notched borders. What it loses in extent it gains in thickness, becoming mammillated or rugous, of a brownish color, softening gradually until it is of a pultaceous consistency. Its borders are continuous with the membrane lining the rest of the cavity. The mammillated projections are due to vascular dilatations. An incision discloses immediately beneath the mucous membrane a hollow areolar structure, resembling erectile tissue. As time elapses these projections become atrophied, the surface shrinks and is not distinguishable. The serotine membrane is slowly exfoliated, and according to Kölliker, a new membrane is not fully reproduced until about the second or third month. Some authors, particularly MM. Robin and Tarnier, have expressed the opinion that the uterine sinuses are closed after the separation of the placenta by a physiological thrombosis; but Hervieux and Barker claim they are compressed by the contraction of the tissues in which they are imbedded, and that when thrombi are found it is due to the rapid separation of the placenta or some pathological condition in the surrounding tissues.

Inflammation arrests these physiological changes, and gives rise to various modifications, according to its intensity and exciting cause.

Barker says, "If opportunity offers for examination of the uterus in the early stage of puerperal endometritis, we find the internal surface covered with a thick, viscid, reddish coating, consisting of epithelial debris, mucus, blood and pus globules." This is easily removed by pouring upon it a stream of water. The mucous membrane is found thickened; if suppuration has taken place, points of ulceration will be found, in some places extending to the muscular surface. Incising the placental surface, the sinuses are found filled with dark blood, partly coagulated, or with fibrinous deposits, these frequently softened. If the surface be squeezed drops of pus will exude. In a case that came under my care the whole vagina and, I have reason to believe, a post-mortem not being permitted, the uterus, was lined with a diphtheritic membrane. Such deposits have been described by German writers, also by the late Dr. Parry, in an epidemic that occurred at the Philadelphia Hospital. The

odor is strong and offensive. In the severe cases, with greenish-black putrilage, it is excessively fetid. When we have the interior covered with a yellowish-green exudation, firmly or loosely agglutinated, so detached as to appear corrugated, the mucous membrane beneath reddened, tumefied, partially softened, and the exudation interpenetrating the placental surface, giving it an ulcerated appearance, Rokitansky calls it uterine croup. A more severe condition, with the internal surface covered with a thin, opaque, green-brownish or dark chocolate or coffee-colored product, and the tissues beneath converted into a fetid pulp, he denominated uterine putrescence.

Endometritis may occur without invading the muscular walls, but Klob concludes that metritis in a majority of cases is consequent upon inflammation of the uterine mucous membrane. Rokitansky believed it to consist of or begin as a phlebitis of the uterine sinuses. These sinuses, particularly of the placental surface, as a result of phlebitis, become filled with dark, partly coagulated, blood or fibrinous concretions. This matter breaks down, pus is formed, the surrounding tissue is destroyed by ulcerative action, and abscesses are formed, generally isolated and limited, but sometimes forming large collections of pus. Sloughing of the walls of these abscesses occurs internally or externally. The former is more favorable; if into the abdominal cavity, peritonitis is at once set up. It may sometimes take place into surrounding viscera that have become adherent.

Says Barker, "In severe epidemics true gangrene of a portion of the uterus is not infrequently met with. It may be recognized by a black or livid portion surrounded by a more or less unequal fringe of red, by the disorganized detritus and the gangrenous odor. It more frequently affects the cervix than the body; the mucous membrane than the muscular tissue."

When we remember the peculiar modifications the uterus undergoes during gestation, the great development of its mucous and muscular tissues, particularly the vascular apparatus, the contractions and compression it undergoes during parturition, and the operations that are often necessary for the removal of the fœtus and placenta; the immense quantity of blood at times lost, and the rapid retrocession of its tissues after delivery, is it surprising that the tissues are liable to morbid processes?

The causes are divided into three classes: 1. Imprudence, as rising from bed prematurely. In a case of mine a fatal attack was induced by stepping on a bare floor on the fifth day. 2. Traumatic lesions of the cervix, placental seat, or muscular walls of the uterus. 3. Toxæmia—as uræmia, septicæmia, pyæmia, and particularly the special poison of puerperal fever. The latter is the special cause we have to combat in the wards of a large hospital. In some epidemics no metritis is present. The most prominent symptoms are pain, increased volume of the uterus, decreased or excessive and very offensive lochia, chill, increased temperature, rapid pulse and cessation of lactation.

The pain resembles after pains, but more continuous. If severe, and occurring on the second day, should require careful attention. It differs from the agony of peritonitis, being usually dull and obscure, increased by motion or pressure. Some cases occur in which pain is only elicited upon deep pressure.

Increased volume is a symptom never absent. The uterus is sometimes found on the second day six inches above the pubes, and may still be felt above the pubes by the fifteenth to the twenty-fifth day. The size is due to tumefaction, as well as arrested involution.

In violent attacks the lochia is sometimes suppressed. Its return, normal in appearance and quantity, may be regarded as a favorable symptom. If, however, we find it purulent early, or if the sanguineous discharge continues longer than the first week, or returns after it has once ceased, particularly if its return be attended by febrile symptoms, we should regard it as a grave symptom. The simple disease is rarely ushered in by a chill or excessive febrile symptoms. If it has gone on to the suppuration stage, we will have recurring chills. If gangrene be developed, prostration becomes extreme, the face pale, the surface covered with a clammy perspiration, the pulse is feeble, respiration hurried, extremities cold, and the lochia horribly offensive. In epidemics, violent and severe cases run their course in a few days. The less severe form is longer in duration, but attended with great danger; suppuration commences early, gangrene, peritonitis or phlebitis. Such cases, however, sometimes recover. I am confident that the uterine croup of Rokitansky, or a less severe form of inflammation, occurs more frequently than is suspected, and passes into chronic metritis or the "areolar hyperplasias" of Thomas, or is the cause of the uterine flexions that frequently follow confinement.

In a case with decreased lochia, quick pulse, and more or less fever, it would be well to give—

℞. Pulv. ipecac, co., gr.x
Hydrarg. chlor., mit., gr.v. M.

at once, and direct a turpentine stupe over the abdomen, to be retained as long at it can be borne, and followed by cotton saturated with laudanum. Opium should be given in sufficient quantity to relieve pain. If the tumor has not decreased in two or three days a blister should be applied, and a combination recommended by Barker of—

℞. Ext. ergot., fl., Squibb's,
Tinct. nucis vom.,
Tinct. ferri chlor., āā f.℥ ss
Glycerin.,
Syr. aurant. cort., āā f.℥ j. M.

Sig.—A teaspoonful every four hours.

The most effective agent, however, in the treatment will be vaginal, or even intrauterine injections. For this purpose we may use warm water, with Labarraque's solution, acid carbolic, potass. permanganate or acid salicylic. If the lochia be purulent they should be used five or six times daily. If fetid, intrauterine injections should be used. For this purpose the fountain syringe should be used, as the ordinary syringe, by its force, would endanger the uterine mucous membrane. Precautions should be taken to prevent the entrance of air into the uterine sinuses, also to provide a ready exit for the liquid from the uterine canal. The latter can be done by passing a double canula, or a soft catheter may be passed alongside the syringe tube.

In the case that heads this paper a marked improvement of all the symptoms was noticed during the time the intrauterine injections were made.

Nutritious food, stimulants and quinine should not be omitted.

In the suppurative and putrescent forms our main reliance, in connection with intrauterine injections, should be upon quinine and alcohol.

AN EPIDEMIC OF SCARLET FEVER.

BY L. N. DAVIS, M.D.,
Of Farmland, Ind.

On account of a recent outbreak of scarlet fever in our locality, which has within the last month or two assumed fearful dimensions and alarming malignancy, I ask leave to report a few cases of the severest type.

The disease had been prevalent, to a greater or less extent, in our town, since the 1st of December, 1878. It was of the mild, regular, or simple form. Not a single death resulted in from twenty-five to thirty cases which I treated, although we had nephritis, dropsy and adenitis, in no less than four or five of the number. So mild, indeed, was the type, that many physicians sneered at the idea of its being scarlet fever, the rash in many cases being poorly defined, but in most of them entirely absent. Throat symptoms, though present in all of the cases, were far from being prominent in many; and the febrile movement was but slight. The epidemic seemed to have expended its force; for there had been a lull for about a month, when all at once it received new impetus, and broke out with increased virulence. As several victims were imbued with the fatal contagium from the same source, I shall attempt to give the cases in the order in which they occurred.

April 23d. Dr. Maltbie and myself operated upon Willie Sumwalt, aged 9 months, for hare lip. We completed the operation at 5 P.M. At 8 A.M. next day we found him with a temperature of 104°, and thickly covered with the scarlet rash. Extensive cellulitis and adenitis followed, in consequence of the wound of the lip. The inflammation abated, however, by the sixth day, with proper applications, and the fever also, but the infant died on the tenth day of its sickness, from failure of strength.

April 24th, or twenty-four hours after the child was attacked, the mother, Mrs. Sumwalt, aged 21 years, took the disease, attended with the severest symptoms during its whole course; temperature ranging from 101° to 104°, pulse from 100 to 150; nausea, vomiting, diarrhœa, dry, dark tongue, sordes on the teeth, hemorrhage from the throat, delirium, subsultus, and finally adenitis and suppuration of the cervical glands. She is now recovering.

April 27th. Dr. R. T. Maltbie, aged 28 years, who assisted in the operation on the child, and who assisted also in dressing the wound afterward, took scarlet fever. The Doctor was not possessed of a robust constitution; was an ardent student; had just finished his last course of lectures, and no doubt had applied himself more closely than was promotive of good health. He was a lover of the profession he had chosen; prompt to every duty pertaining to it; was present to lend assistance in every emergency, and give aid wherever and whenever it might be required, little thinking of his own safety and of the fearful danger to which he was exposing himself daily.

April 28th, 8 A.M. I found his temperature 100°, pulse 102, with severe vomiting and retching; rash well defined, but not dusky. I gave him ice to chew, lemonade to drink, sol. chlorate potassa, with two drops fl. ext. belladonna every six hours; move the bowels with seidlitz powder. 9 P.M. Temperature 101°, drowsy, smarting in

passing water. The urine has a dark, sooty appearance, and is loaded with albumen. I ordered the surface sponged frequently with cool water.

April 29th, 8 A.M. Temperature 102°, pulse 108. 9 P.M. Temperature 104°, pulse 132; comatose. Continued the treatment, and gave four drops each of tinct. digitalis and aconite in a teaspoonful spts. mindererus, every three hours; used carbolized spray in the mouth and nose.

April 30th, 5 A.M. Temperature 103°, pulse 126; passes a moderate quantity of urine, but attended with tenesmus, and still contained albumen. I gave cold pack, and quinia in three-grain doses, every three hours; brandy and milk as freely as could be taken.

May 1st. Rested but little last night; was troubled with singultus and dyspnœa all night. Singultus continues this morning. The skin of the whole surface is intensely red, swollen and sore; conjunctiva very much injected; temperature 102°, pulse 132. I moved the bowels again with saline; gave 5 grains of musk, which partially controlled the hiccough. Tonics, milk, sponging, and grease to surface continued.

May 2d. Temperature 99°, pulse 132; eruption fading on the chest; tongue dry and dark; but little rest last night; more or less subsultus and delirium. Sponged the surface with tepid water; omit digitalis and aconite.

May 3d. Passed sufficient quantity of urine in twenty-four hours, but it is dark and contains albumen; was very restless and delirious during the night; drinks milk and broth pretty freely; temperature normal; pulse 132, and feeble.

May 4th. Great restlessness all night, with dyspnœa and delirium. Temperature normal, pulse 136. Brandy and milk to be given freely.

After the most restless and wakeful night that human nature can possibly experience, in its last futile efforts against disease, he expired at 7 A.M., May 5th.

April 25th. Sophia Thornburg came to work for her sister, Mrs. Sumwalt. Three days later she took scarlet fever, which was as severe in character as the case of her sister, above described. She escaped without renal or other complication, and recovery seemed complete by the end of fifteen days.

April 27th. Miss H. F., aged twenty, who sat up at Mrs. Sumwalt's three days previous, took scarlet fever. Has had the disease once, and made a favorable recovery in a few days.

Three days after her return home her little nephew, aged four years, took scarlet fever in its most aggravated form, followed by suppuration of the cervical lymphatics; and finally, three weeks later, by renal dropsy, which eventuated fatally on June 9th.

May 22d. Rose T., aged two years, took scarlet fever. Recovered in five or six days, without complications.

Her father, who had visited his sisters at Sumwalt's, had been sick the preceding five or six days, with sore throat and fever, which probably was true scarlatina; though no physician saw him, and of this we cannot be positive. The little girl had also been exposed to her aunt, though she (the aunt) had been well for about ten days, and had taken the utmost pains to boil and clean every article of her clothing; as well also to resort to frequent ablutions of her own person before coming home. Consequently the exact source of contagion and time of exposure cannot be arrived at in this case.

The same may be said of the following cases: although of a different family, the two (father and son) live on the same farm, and their families intermingle daily; so that the exposure of one child of either family might be considered common to all of both families.

The time of the attack in the children of the two families shows conclusively that the seeds of the disease were sown about the same time; for the next day (May 28th) three girls of Isaac T., aged respectively four, six and twelve years, were attacked.

The disease was ushered in with severe vomiting and diarrhœa, and all of them died. The oldest on the sixth day, from prostration, induced by high temperature and intense blood poison. The second on the sixth day, from extension of a diphtheritic deposit into the larynx. The youngest on the 12th day, from extensive swelling of both sides of the neck, and probably œdema of the glottis.

June 1st. Alva T., aged eight years, brother of the little girls, was attacked. The symptoms during the first two days of the disease were as aggravated, apparently, as were those of any of his sisters. A blister was applied over his stomach, to control the vomiting, and five grains of sulphur with equal quantity of pepsin were given every four hours. In three days the boy began to sweat; the vomiting ceased; the tongue cleaned off moist, and only moderately red, instead of very dry and dark or intensely red, as it had been wont to do; and he made a rapid and favorable recovery without complication or sequela.

A few days later his brother, Elmore T., aged 15 years, was attacked with scarlatina. He had

been using sulphur for several days prior to the attack. It was continued. The boy did not take his bed at all, and in five days was plowing corn.

May 27th. Mary T., aged 18 years, at full term of pregnancy, was attacked.

May 28th. Found temperature 99°, pulse 100; throat sore and rash well defined; tongue lightly furred, appetite good.

May 29th. Temperature 101°, pulse 120; tongue heavily coated, with red tip and edges.

8 P.M. Was called upon to wait on her in confinement. After a protracted but easy labor, she was delivered at 10 A.M. the next day. My friend, Dr. Keener, delivering the placenta, we left her in good condition and excellent spirits.

May 31st. Temperature 100°, pulse 112; lochia normal, appetite good, and she was quite jovial. Gave emulsion of turpentine three times a day, and tinct. ferri mur. in five-drop doses after each meal.

June 1st, 10 A.M. Temperature 103°, pulse 120. Rested poorly last night; pain in back and loins. Bowels somewhat tender. Lochia natural in quantity and character. Light secretion of milk. Surface has a scarlet hue; tongue red strawberry appearance; bowels moved twice with oil. Ordered turpenine stupes to abdomen; vaginal injection of carbolized water every five hours; three grains quinia and Dover's powder, each, every four hours.

June 2d, 11 A.M. Temperature 103½°, pulse 136. Moderate secretion of milk. Severe rheumatic pains in the joints of the upper extremities, so that it becomes utterly impossible to move either arm. Lochia still continues; appetite fair; copious secretion of urine.

June 3d, 9 A.M. Temperature 104°, pulse 126. Rested poorly last night; was short of breath and delirious. Three loose, spontaneous discharges from the bowels; lochia diminished in quantity, and more offensive; milk drying up; œdema of and rheumatic pains in the legs. Added opium, in moderate doses, every six hours.

June 4th, 9 A.M. Temperature 102½°, pulse 115; flushed and hectic appearance of cheeks.

June 5th, 8 A.M. Axillary temperature 105°, pulse 125. Great restlessness, dyspnœa and thirst, all night. Chews ice constantly, to satisfy the thirst and cool the mouth and stomach. Decided tenderness and great distention of the bowels. Also very much troubled with strangury. Urine contains a large portion of albumen. Placed a large blister above the pubis; gave four drops each of tinct. of digitalis and aconite every two hours till temperature and pulse are reduced. 5 P.M. Temperature 103°, pulse, 102. Tongue so dry and stiff that she cannot protrude it. Blister drew well; not so much thirst nor distention of the bowels.

June 6th, 10 A. M. Temperature 102°, pulse 96. Rested better last night. Took suddenly, at 6 P.M., while eating some broth, with extreme prostration and congestion, during which she could not speak nor swallow. Pulse was not discernible at the wrist, and every symptom was but the premonition of immediate collapse. Dr. Keener and myself arrived, and ordered whisky as freely as could be poured down the throat without strangulation, but little expecting that reaction would ever come up. We were mistaken, however, for reaction did come up in the course of an hour; and with it came the most agonizing, burning, peritoneal pains, during which the woman would scream till she might have been heard more than a mile. They were quieted by a large dose of morphia hypodermically. The blister was again laid higher up on the abdomen, thinking it might assist in controlling the lancinating pains. Morphine repeated sufficiently often to control the pains.

June 7th, 10 A.M. We found the axillary temperature 105, pulse 150 and very feeble; dark cyanotic appearance of the face and extremities, and profound coma. Morphine given when necessary to control the pain, which was unbearable when the drug was omitted.

June 8th. Temperature 102°, pulse 120. Less coma. Has taken little nourishment. Less abdominal pain. Not more than three ounces of urine secreted in the past twenty-four hours, and that very dark and albuminous. Dark gangrenous ulceration of both hips; also extensive vulvitis. Emollient poultices applied to the vulva, and carbolized lard to ulcers; placed her upon an air cushion.

June 9th, 10 A.M. Temperature 101°; pulse 96; rested more last night; about six ounces of urine secreted in past twenty-four hours. Gave a solution of acetate potassa., with ten drops of the fluid extract of jaborandi, every three hours.

June 12th. Temperature 102°; pulse 106; urine very scanty and dark. Bowels inclined to be loose, and are very tympanitic; expels large amount of gas with each passage; had two or three involuntary passages during the night. Turpentine emulsions resumed three times a day.

June 13th. Had mild uræmic convulsions at short intervals all night. Extremely nervous and comatose; can scarcely be aroused to answer a

question. Used dry cups to loins; sponged the surface with tepid water, and gave three drops each of fluid extract gelsemium and digitalis every three hours, cold applications to the head and mustard to the spine.

June 14th. Symptoms of uræmic convulsions have pretty well disappeared; but very comatose and nervous.

June 19th. Found the right parotid gland very much inflamed and enlarged. Temperature 102°; pulse 96; voids from eight to twelve ounces of urine, on an average, in twenty-four hours, which is very dark in appearance, and heavily charged with albumen. Ulcers on the hips show but little tendency to heal, present a sloughing, unhealthy appearance. The labia are most intensely swollen and red. Cloths wrung out of a strong oak ooze are applied thereto; gave teaspoonful of extract of malt every three hours. She improved steadily from this time, and at present writing (June 27th) her recovery seems to be a foregone conclusion. The extensive blistering, which resulted in a deep sore, might be regarded by many as an entirely unwarrantable procedure at the time, and under the circumstances, but, in my judgment, it was the important factor in the treatment, and that which prevented a fatal issue of the puerperal peritonitis.

The case has been one of rare interest and remarkable severity; and during its whole course there has been a degree of fortitude and endurance upon the part of the woman seldom seen in any case. Had this not been the case death would have closed the scene long ere this, and the sad anticipations of her relatives, nay, physicians also, would have been fulfilled. Her tenacity of life and tranquillity of mind, the earnest pleading look for assistance when possible, or perfect resignation when no assistance could be rendered, were such as to inspire the physician with a perfect knowledge of the unlimited responsibility which rests upon him, and to make him feel that the medical profession is one of the grandest and most noble of all callings.

Her offspring, though feeble at first, is now quite healthy, and, according to my judgment, has escaped the disease. Upon this point, however, there might be some discussion, for, of course, the skin was red, and subsequently there was slight desquamation; but there were not more redness and desquamation than we have in many newly born infants in which we have no reason to suspect scarlatina, and these were the only indications of the disease in this case. Consequently, I feel perfectly justifiable in asserting that the child was not contaminated with scarlet fever at the time of its birth, nor has it been since. It nursed its mother but little, as there was but the smallest amount of milk secreted at any time. My treatment during the epidemic has been expectant. Suffice it to say that, contrary to the advice of Dr. Black, of Newark, Ohio (volume XL, No. 10, REPORTER), I did not have recourse to "ipecac in diaphoretic, hydrargyrum cum creta in laxative, and nitrate of potash in diuretic portions," for in all of the severe cases we had vomiting and diarrhœa, more or less, and generally severe from the incipiency of the disease; moreover, I confidently believe that had I resorted to this treatment I could have had severe if not fatal cases of all of them. Neither do I find that buchu, acetate of potash, juniper, or any other diuretics furnish the least protection against nephritis, and I verily believe that they are decidedly injurjous after its onset.

Nourishment has been given *ad libitum*, and the following are among the medicinal agents and means used: sulpho-carbolate of sodium, tinct. baptisia, carb. ammonia, chlorate of potash, quinia, tinct. iron, belladonna, digitalis and aconite; frequent sponging with cold water and grease to the surface, and cold pack; ice internally; local application of iodine, ammonia, etc., to enlarged glands; cathartics, generally castor oil or saline, when indicated; diuretics, acetate potash, buchu, etc., when there was the least hope of success. Every one of these remedies, and every combination of them that I have been able to make, has signally failed; so much so, indeed, that I am almost constrained to believe there is not the vestige of virtue in them, however skillfully applied and sedulously carried out.

I am an enthusiastic believer in the efficacy of the sulphur treatment. I have observed its action in three cases only, two of which are given, and the results in these, I must say, were marvelous, all that could be desired. I shall not theorize as to the modus operandi. The clinical fact which the results of its use establish is sufficient; and one clinical fact is worth a whole volume of flimsy theory, to the busy practitioner.

The incubation, it will be observed, was exactly three days, in four of the cases which I have given in which the exact time of exposure was positively known.

—Mrs. Partington has been reading the health officer's weekly reports, and thinks "total" must be an awful malignant disease, since as many die of it as all the rest put together.

Medical Societies.

NORTHERN MEDICAL SOCIETY OF PHILADELPHIA.

At the meeting of the Society held on the 28th of March, 1879, Dr. E. E. Montgomery read a paper on

Puerperal Metritis,

which is given on page 23.

Dr. J. B. Walker has seen a number of cases, and believes the disease to be more frequent than reported, often passing unrecognized. In the Philadelphia Hospital it is rare for a woman to pass through the puerperal condition without more or less inflammation of the womb. The most common cause in hospital is toxæmia, more, perhaps, than in private practice. He would like to emphasize the value of local blood letting in certain epidemics. Began practice with the idea that arterial sedatives could do all that it was possible to do by blood letting. In the midst of one of the frequent epidemics at the Philadelphia Hospital, he was induced to try leeches, because the death rate had reached an average of 66 per cent. of all attacked. The first case tried was that of a thin, feeble, asthenic woman, just attacked with symptoms so severe as to give little hope with the then high rate of mortality. Twenty-five ounces of blood was taken from the epigastrium by leeches. The result was immediate, and recovery so rapid (only three days longer than the normal puerperal condition) that it was resorted to in all the following cases of that epidemic, with a decrease of one-half in the death rate, or to thirty-three per cent. That the epidemic influence was not gone or lessened was shown by the violence of the onset and the number of cases attacked remaining the same until removal to another building. The other elements of treatment remained the same as before applying leeches.

Dr. J. T. Eskridge reported five cases from private practice, all of which recovered. They were treated by vaginal injections of carbolic acid, turpentine stupes, calomel and bicarbonate of soda, to free the movement of the bowels, and tinct. veratrum viride in full doses, five or six drops every hour, until the pulse fell to sixty, or even fifty, per minute. He believes there is no danger with this remedy, because alarming symptoms come on long before there is real danger. It is easy to rally the patient from the depression, if too great, by brandy.

Dr. S. Updegrove believes that metritis may exist before and during labor. An adherent placenta is a sign of an already diseased condition of the womb. He agrees with Dr. Eskridge in the employment of veratrum viride, which should be watched very closely, but when so watched it is preferable to blood letting, because it allows the production of a greater effect than one dares to produce by leeches.

Dr. W. M. Welch has not had metritis follow as a consequence of removal of adherent placenta, nor the use of forceps or other obstetric operation. It is frequently caused by toxic agents, as proved by its greater frequency in hospitals, and he would say, therefore, blood letting was not indicated. Post-mortem appearances also argue against blood letting. He relies upon a supporting plan of treatment—alcohol, quinine, and especially opium; would not like to undertake a case without opium.

Dr. E. R. Stone witnessed an epidemic while a resident in the hospital. Veratrum viride and opium were used freely and pushed to their full effect, but with very unsatisfactory results, nearly all dying, until he came to look upon a woman as doomed from the day of the attack of childbed fever.

Dr. E. E. Montgomery believes that all operations requiring the introduction of a foreign body into the womb render the woman more liable to an attack. His first twelve cases were seen while a resident in the hospital. The first three died. He then became bold in the use of veratrum viride and morphia, with the result of not losing a fourth case. Once he reduced the respirations to five per minute.

Hospital patients all have a tendency to an asthenic condition; therefore he was opposed to blood letting among them. When the pulse became weak he would give digitalis.

In all epidemics the early cases were more violent, which might account for Dr. Walker's success.

On the Influence of Singing upon Health.

In the *Allgemeine Medicinische Central Zeitung*, S. M. Wassiljew reports:—

In the examination of 222 singers, from nine to fifty-three years of age, as to the growth of the body, dimensions of the chest, and breathing capacity, the following facts were observed:—

The growth of the body advances beyond the twenty-fifth year. The increase, however, is not proportional to the age, but more rapid toward puberty.

Compared to non-singers, the dimensions and excursions of the chest walls were found greater. Both increased with the size of the body, age, and the number of years engaged at singing; in the former more rapidly about puberty; in the latter until the twenty-fourth year.

The expansive power of the chest was found to be intimately connected with the state of the health, being smaller in the intemperate and in persons disposed to phthisis.

The force of inspiration and expiration, and the vital capacity of the lungs, were also found to increase with the size of the body, age, and the number of years engaged in singing; the maximum in each case being attained at about the twenty-second year.

In view of the greater vital capacity of the lungs, the author concludes that singing alone, judiciously conducted, can never produce emphysema.

From the 22d to the 28th years, all the measurements obtained were found to diminish, increasing again from the 28th to the 38th year. As a cause of this phenomenon, the author gives a failing in the nutrition of the body, occasioned by irregular habits of life.

As much as singers are liable to laryngitis, they are exempt from bronchitis.

Emphysema is not oftener met with among them than among non-singers.

The mortality among singers is small. Statistics extending over a period of twenty-five years, exhibit not a single instance of death from phthisis.

Bright's disease of the kidneys is a common affection among singers, even among those who are temperate in their habits.

As a practical application of the results obtained, the author concludes by referring to the beneficial influence the practice of singing might have upon the development of the chest in phthisical subjects, considering it even more efficient, in this respect, than gymnastics.

How to Postpone the Use of Spectacles.

Dr. W. Cheatham writes to the Louisville *Medical News*—

Till lately I have advised the use of spectacles the instant their want is felt; but now we have in sulphate of eserine a remedy (and a safe one, I believe), by which the wearing of glasses can be put off for several years. In presbyopia we have loss of distinct near vision, caused partly by the loss of power in what is known as the ciliary muscle. Eserine is a stimulant to this muscle, producing contraction, and in that way assists in accommodation.

From my results so far I believe that spectacles may be dispensed with for several years after their want is first felt. I usually order eserine sulphat, gr.j; aquæ dest., ℥j; one drop to be put into each eye at bedtime. On account of the artificial myopia produced I order it to be put in at bedtime. It may be dropped in at any time, as the myosis soon passes away.

Besides its employment in glaucoma and other inflammations of the eye, and in presbyopia, I have found it of great use in asthenopic (weak) eyes, depending upon oversightedness and weakness of accommodation, the latter the result of either overwork, general debility, diphtheria, etc.

Spectacles in presbyopia (the loss of near vision from age) always give ease; but there is a certain discomfort from the use of glasses, besides many other objections brought forward by patients, all of which, as a usual thing, can be referred to pride. This pride we should humor as much as possible. If by means of the eserine we can give them as great comfort and preserve their eyes as well as by means of spectacles, I think it proper that we should do so.

Doubtful Utility of the Hot Vaginal Douche.

Dr. A. Reeves Jackson, formerly Surgeon in Chief of the Woman's Hospital of Illinois, writes to the St. Louis *Clinical Record*—

It would seem that, of all the local conditions demanding the especial effects which are attributed to hot water injections, none would be more likely to be benefited by them than vaginitis; yet I have not only been disappointed in every case of this disease in which I have used them, but I am sure that in some their employment was injurious.

Whether the good effects of this remedy in the treatment of uterine disease have or have not been overrated, it is quite certain that there are some drawbacks to its use. For example, several patients have informed me that the douche was followed by great prostration, lasting, in some instances, several hours. Others, again, have been obliged to abandon it entirely because of long continued flushings of the face and throbbing headache resulting from its use.

The experience of others may not correspond with my own, and I feel some hesitation in placing myself in a position not in accord with the popular opinion concerning this remedy, which, at present, is so much in fashion. Nevertheless, I am constrained to say that it has disappointed, in a great degree, the expectations I had formed of its very great efficacy, and which were founded on the high encomiums lavished upon it in various quarters.

Tartar Emetic in Rigid Os Uteri.

This illustrative case is reported in the *Lancet*, by Dr. J. A. Irvine:—

Mrs. B., aged twenty-three, primipara. I saw her on the morning of the 26th of September last. On examination I found the os beginning to dilate and slight pains present. The membranes were intact, and I left her in charge of an experienced nurse. On again visiting her, some hours after, the pains I found still present, but rather irregular. I again examined the os, and found very little advance made since last visit. I saw her again in the evening, it being now altogether twelve hours since the commencement of labor. The os was at this time rigid, and no further dilatation had taken place, notwithstanding the strong and frequent pains. The lips had a hard, ring-like feel, very different from the semi-pulpy os sometimes met with. The patient's strength was good, with but little constitutional disturbance. I determined to give her antimony in small, frequent doses, and accordingly administered one-sixth of a grain of tartar emetic every ten minutes. A few doses thus given produced nausea, and after the fifth dose vomiting took place, when the administration ceased. On examining the os after a short interval, I found the rigidity gone, and the hard ring vanished. As soon as possible I ruptured the membranes, and safe delivery fol-

lowed. The rapid effects of antimony in this case were surprising, and from a similar experience subsequently I believe that the small and frequent doses as here given are the best way of exhibiting the drug. Dr. Hall, of Montreal, recommends half a grain every half hour, but dangerous depression might in many instances supervene.

Poisonous Mushrooms.

Mr. J. A. Palmer has a paper on poisoning by mushrooms in the *Moniteur Scientifique*. He states that there are three different ways in which mushrooms may act as a poison. First, they may produce the effects of indigestible matter, as when the hard coriaceous species is eaten; and even the edible mushroom may cause a similar result, for when it is decomposing it gives off sulphuretted hydrogen gas in quantity sufficient to induce vomiting. Second, mushrooms may be gelatinous or acrid. Third, a subtle alkaloid, without smell or taste, is contained in some mushrooms, as, for instance, in the group of the Amanitæ, and is called amanitin. No antidote has yet been discovered for this poison, and to it most of the cases of death following the eating of mushrooms is due. It is at first slow in its action, but after the lapse of eight to fifteen hours the patient experiences stupefaction, nausea and diarrhœa. Delirium follows, and then death. Mushrooms containing amanitin will impart poisonous properties to wholesome varieties, if both happen to be placed in the same vessel. The poison can be absorbed by the pores of the skin. Mr. Palmer carried in his hand some amanitæ wrapped up in paper, and, notwithstanding the protection which the wrapper should have afforded, he was seized with alarming symptoms.

Diagnosis of Fractures of the Radius and the Clavicle.

In the Edinburg *Medical Journal*, Mr. John Duncan writes—

Let us consider for a moment the diagnosis of the two most common fractures of the body, that of the lower end of the radius and of the middle of the clavicle. They are both due invariably, or almost invariably, to indirect violence. If a person fall upon the palm of the hand he may sustain one of three injuries from the bending backward—a dislocation of the wrist, a sprain of the joint, and a fracture of the lower end of the radius. The first is so very rare as hardly to be worthy of discussion in the present connection. I have only once seen it, and then, as I was manipulating to define the relations of the styloid processes, the joint slipped into position. I cannot say, therefore, from experience, what the exact situation of tenderness is. Doubtless it is over the joint itself; but doubtless also, the diagnosis depends on the deformity.

As to the means, however, of making a comparative diagnosis between the other two, I am absolutely certain. The characteristic deformity of Colles' fracture is marked in at least nine cases out of ten, and there is required for diagnosis nothing more than careful inspection. But in the tenth case the deformity is so slight as not to be easily made out, or is masked by the general swelling. It is in the distinction of these more obscure examples from sprain that tenderness plays its rôle. If there be a fracture, the pain on pressure is most severe above the level of the styloid process of the radius, both before and behind; if there be a sprain, the pain is in the region of the joint. It is impossible to have anything more definite and precise.

In fracture of the clavicle, pain on pressure is also pathognomonic. You have only to run your finger along the line of the bone. No doubt, in all cases, for purposes of treatment, you ascertain whether deformity is present. But that is not necessary for diagnosis, and its absence is not a source of embarrassment. Tenderness here is the important sign; swelling and deformity come next, and no other sign—neither mobility nor crepitus—need or ought to be sought for.

Aphorisms on the Nature and Treatment of Gonorrhœa.

Dr. Louis Bauer lays down the following, in the St. Louis *Clinical Record*:—

1. Gonorrhœa is indisputably a local disease.
2. The cause of gonorrhœa is local also, and of ephemeral duration.
3. Gonorrhœa is inflammatory in character, and if not disturbed by stimulating treatment, limited to the anterior portion of the urethra.
4. Primarily gonorrhœa affects the mucous membrane only.
5. Whatever may be the primary disintegration of the urethral lining by gonorrhœa, the structures involved are endowed with the power of spontaneous repair, that is to say, the reproduction of epithelium.
6. The reason why the erythematous inflammation of the urethral canal deserves special consideration and treatment is its special function to serve as an aqueduct for a saline fluid (urine).
7. The only rational indications for the treatment of gonorrhœa, are:

a. To protect the raw surface of the mucous membrane against contact with urine.

b. To dilute the urine by frequent bland beverages, warm (alkaline) baths, and the like.

c. To reduce the inflammation and the hyperæsthesia of the nerve papillæ.

The Use of Damp Cotton in place of the Surgical Sponge.

Sponge is sandy, rough, of animal origin, and dangerous. Dr. W. H. Mays, in the *Western Lancet*, urges in place of it damp cotton. It is prepared as follows:—

Take the absorbent cotton of Hance Bros. & White, and without disturbing the layer-like arrangement in which it comes, squeeze it as dry as possible out of carbolized water, strength one in forty. Then carefully separate it in layers, and divide it into pieces the size of the hand. These pieces should be pulled apart until they are light and flossy, and then placed in a pile ready for use. Each piece is used but once, and when saturated with absorbed fluid, is thrown into a bucket under the table and a fresh wad taken.

In ovariotomy, the cul-de-sac of Douglas plays the part of a pocket or well into which the effused fluid gravitates. It is necessary to frequently introduce an absorbent to soak up the contents of this reservoir, and I find that by ensheathing the fingers in a layer of damp cotton (like an old-fashioned fingerless mitten) the open hand can be passed easily down, the bowels pressed gently aside, and the deposit reached and absorbed without any roughness such as would accompany the thrusting of a sponge into that cavity. To dry the intestines they can be laid on a thin cushion of this cotton wrapped round the fingers of the left hand, while touched softly with a wad of the same held in the right.

I apprehended at one time an objection to this new absorbent in the occasional separation of a filament or two, which, being left behind, might cause trouble. But such fear is groundless. The coherence of a mass of damp cotton is something surprising; to draw away a few strands is not nearly so easy a task as might seem to those who never tried it. Applying it to the surface of the tongue, as a test, it is found that none becomes detached, and no part is quicker to detect the presence of a stray hair. In a tuft of damp cotton there are no loose filaments.

The superiority of this absorbent over the foul, harsh sponge ought to need no labored demonstration.

Rules for Managing the Third Stage of Labor.

The following precepts are laid down in the Chicago *Medical Journal* on this subject, by Prof. De Laskie Miller, M.D.—

1. Contractions of the uterus after the birth of the child are essential to complete the detachment and expulsion of the placenta first, and second to compress the sinuses, and thus to prevent hemorrhage.
2. Periods of rest during this process are important, to permit the closing of the disrupted sinuses by sealing with coagula.
3. The early agitation of the uterus by kneading and compression, would defeat the conservative forces of nature in this stage of natural labor.
4. Withhold ergot till the placenta is detached.
5. Deliver the placenta by bringing it down edgewise with the hand, and not by traction upon the cord.
6. Inertia of the uterus without hemorrhage requires time and restoratives.
7. For inertia of the uterus with hemorrhage, introduce the hand to deliver the placenta, and at the same time secure contraction.
8. Irregular contraction is best overcome by moderate force, continuously applied.
9. Abnormal adhesion requires artificial interference as soon as the diagnosis is made.

Incontinence of Urine.

Mr. J. Scott Battams (Royal Free Hospital) calls attention, in the British *Medical Journal*, to a plan recommended by Dr. M'Intyre, of treating incontinence of urine in children by diminishing their consumption of animal food, flesh meat in any form being allowed but three days in the week. This treatment was quickly and entirely successful. Mr. Battam's experience of this plan of cure is limited to three cases; all were obstinate and of long standing. Belladonna, iron, strychnine, etc., were tried in vain. He continued the iron, and interdicted all flesh meat, including beef-tea, broth, etc. He also advised that very little fluid should be given in the latter third of the day, and that they should pass urine before going to bed. At the end of a week two of the children had quite recovered, the third also had only transgressed twice. Two of these patients came under observation three months afterward, and they still continued well; and as the third was not brought to the hospital, he probably had not relapsed. In another case, belladonna and nux vomica were rapidly curative. He was a youth aged 16, who had suffered from nocturnal incontinence for three years, since leaving school; he was well grown and nourished, but rather torpid mentally. He had always had good health. The genital organs were exceptionally small, the prepuce not too long. Mr. Battams prescribed ten minims of tincture of belladonna, and five minims of tincture of nux vomica three times a day. A fortnight later he had had no incontinence for a week, and a month later he was still well.

Antiseptic Treatment of Wounds, and its Method.

In the treatment of wounds, not only were our earlier surgeons perplexed as to the cause of the different behavior of subcutaneous and open wounds, those healing by first intention, these by copious suppuration, but especially did they dread those accidents of pyæmia, erysipelas, hospital gangrene. Whence their cause they could only conjecture.

To Billroth is due the credit of having led the way to a more rational conception of those conditions. He taught that their cause lay in the development of specific poisons by the decomposition of the fluids of the wounds, and their reaction upon the system at large, by entering the circulation.

Later, more light was brought on the question, by the discovery of minute organisms in all the products of decomposition and fermentation; and when, still later, those organisms were also found in other fluids, even water and air, and adhering to almost every object examined, the real source of infection to wounds could no longer be unknown.

From the practical application of this knowledge there follows:—

All wounds, large or small, subcutaneous or open, possess the inherent property of healing by first intention.

The healing of wounds is prevented, in the first place, by the entrance of those organic germs, not so much directly through the air, as through dressings, instruments, fingers of surgeons. In the second place, the healing is retarded by the accumulation of the fluids at the bottom of the wound. The dangers which will arise from such conditions will be prevented in two ways. First by keeping from the wound those sources of infection, the principle of the antiseptic treatment, as followed by Lister in England, and Volkman

in Germany. Secondly, by establishing a free discharge for all fluids forming in the wound, the open-wound treatment of Billroth. Applying the principle of the antiseptic treatment in practice, the surgeon must keep before him three cardinal points:—

1. Most careful cleanliness and disinfection of all things coming in contact with wounds.
2. Free discharge of all secretions.
3. Rest of the wounded parts.

To accomplish these objects, not only the wounds, but all the parts around them, must be carefully washed. The hands of the surgeon, especially the nails, must be cleaned at every operation, so also the instruments. Sponges should be rendered free of sand and repeatedly washed in disinfecting solutions. The same may be said of bandages and other dressings. They should, if possible, always be new. Among the numerous antiseptics and disinfectants, a common and efficient one is a high temperature. Various are its application to practice. It forms a most efficient means of cleaning instruments with rough surfaces, sounds, forceps, catheters. Cutting instruments cannot be subjected to this process, for obvious reasons.

The Hypodermic Use of Carbolic Acid in Piles.

Prof. E. Andrews, M.D., of Chicago, says, in the Michigan *Medical News*—

The evidence in my hands points to the conclusion that if the following rules be observed the hypodermic injection of piles is less painful and fully as safe as any other operation:

1. Inject only internal piles.
2. Use at first only one part of carbolic acid to twenty parts of the excipient, and stronger solutions only when these fail. Inject only two to four drops at first, and repeat with larger doses if needed.
3. Inject very slowly, smear the parts first with unguent, to protect them from accidental dripping, keep the pipe of the syringe in the pile for a few moments, until the fluid becomes fixed.
4. Treat only one pile at a time, and allow from four to ten days between the operations.
5. Dangerous hemorrhage has occurred, as in other operations, from the patient proceeding at once to active exercise. He should be confined to bed the first twelve hours, and returned to it subsequently if the parts inflame much or the pile suppurates or mortifies.

This great western epidemic of pile doctors is one of the most interesting events in the history of surgery, and seems to have resulted in the addition of a really valuable improvement to our resources.

Treatment of Inflamed Joints, etc.

Mr. Rushton Parker writes to the *Lancet*—

In synovitis of the knee, patellar bursitis, and also boil, abscess, or other inflammation, cutaneous or subcutaneous, in the same anatomical neighborhood, I have found that similar treatment is, in principle, and often in detail, appropriate to all, and that each condition in its own way gives evidence of the part played by rest in the process of inflammatory resolution. Any one of these affections can be treated, as a rule, without laying the patient up, and is, if painful, immediately relieved as soon as the knee is fixed in the straight position by a back splint, or by an abundance of plasters enveloping the joint and continued a moderate distance above and below, or by a combination of both. A continuance of this treatment, not tightly applied, but so as to prevent or greatly to limit flexion, is not only comfortably borne by patients going about, but is generally followed by complete resolution. I cannot attribute its good effect to any compression of the plaster; witness the cases where the affected part was uncovered from first to last, a practice which I invariably adopted formerly. In each case there is an inflammatory condition which with each flexion of the knee joint is either compressed (as in the case of synovitis, bursitis, or abscess), or pulled upon (as in boil, wound, etc.). The mere cessation of this movement not only allows the patient to get about painlessly within certain limits, but, by ceasing to aggravate, permits the resolution of the inflammation. The abscess may, of course, require incision or aspiration, and the same is true of the serous fluids; in fact, much time is often saved in synovitis, and always in bursitis, by aspirating at once after fixing the joint; while in some cases it is indispensable.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——Dr. Horatio R. Bigelow, of Boston, has made a very careful anatomical study of the chorda tympani nerve (Reprint from Archives of Medicine).

——Dr. C. W. Dulles, in a paper read before the Medical Society of Philadelphia county, on the meaning of a chancre, spoke in favor of defining it simply as "the initial lesion of syphilis," and thus avoiding the confusion of signification which many writers attach to that term.

——"Thevetia Iccotli and its Glucoside" is a pamphlet of a few pages, by Dr. David Cerna, containing a study of this Mexican plant and its proximate principle. The latter is a powerful poison, producing death by asphyxia and by cardiac paralysis. Locally, thevetin produces contraction of the pupil. Its medical value is undetermined. The Mexicans use the plant in making an ointment for hemorrhoids.

——Dr. Henry B. Sands has come out with a sharp reply to Dr. F. N. Otis' polemical pamphlet on spasmodic stricture of the urethra, which we noticed a few weeks ago. The following is his concluding sentence:—

"I think I have said enough to show that the theory of spasmodic stricture, as taught by Dr.

Otis, is unsupported by trustworthy evidence, and has led to serious errors in practice. Believing the doctrine to be false, and the practice dangerous, I should feel that I was recreant to my trust as a public teacher if I failed to oppose the one or denounce the other."

BOOK NOTICES.

The Pharmacopœia of the British Hospital for Diseases of the Skin, London. Edited by Balmanno Squire, M.B., Lond. pp. 80. London, J. & A. Churchill, 1879.

This useful publication will be appreciated by dermatologists. The different branches of the London Hospital for Diseases of the Skin include specimens of almost every variety of disease known, and the medical care they receive is the best in the world. Hence, the value of the formulæ which this long experience has shown to be the most effective. The directions are concise, and only those prescriptions for skin treatment are given which are not provided in the British Pharmacopœia. Mr. Squire is already well known as a judicious compiler in this direction.

Lessons in Laryngoscopy and Rhinoscopy; Including the Diagnosis and Treatment of Diseases of the Throat and Nose. By Prosser James, M.D., Lecturer on Materia Medica and Therapeutics at the London Hospital, Physician to the Hospital for Diseases of the Throat, late Physician to the North London Consumption Hospital, etc. Third edition. Illustrated with hand-colored plates. London, Balliere, Tindall & Cox, 1879. 12mo, pp. 160, illustrated.

Dr. James has been familiar with the subject of which he writes from the earliest days of laryngoscopic investigation. Indeed, he is one of the few who dimly conceived the idea of laryngoscopy, but failed to appreciate its importance before its value had been incontestibly demonstrated by Czermak.

The lessons in laryngoscopy present quite a full series of chapters on apparatus, manipulation of instruments, description of images, history of the subject, diagnosis, therapeutics and operations, illustrated with fifty-seven excellent wood cuts and five hand-colored plates. The plates give an approximately accurate appreciation of the real images, but, like all the colored plates which have appeared since those of Fürch, they are inferior to the admirable illustrations of that author. The colored rhinoscopic image retains Semeleder's incorrect outline of the pharyngeal orifice of the Eustachian tube, while the nares enclose representations of superior turbinated bones certainly anomalous. It appears as though each nasal passage contained two middle turbinated bones, with an upper one above (unmarked in the diagram) and an inferior one below. The wood-cut on page seventy is more accurate in this respect. Some of the designs in the volume are admirable. For example, the use of the word "glottis" (Fig. 25), as represented in a mirror, to teach the character of the apparent inversion of the image, and the series of enlarged views of the laryngeal image, Fig. 29 of which possesses the rare merit of correctly indicating the position of the arytenoid cartilages. Fig. 28, however, designates the thyroid as the cricoid cartilage.

A great deal of useful information is presented, and that derived from actual experience, the best guide for what is required, and this is not to be obtained in any other volume. We regret that the limited space at our disposal precludes more direct reference to these points, and hope that those interested in the subject will procure the Lessons, which comprise the handiest manual in the vernacular, and should be accessible to ever student of laryngoscopy and rhinoscopy. The language is good, the sentences are terse and to the point, and opinions are decided and reliable. Various continental and American workers receive prominent mention, but we fear that scant justice has been done to British colleagues.

The reader will be surprised to find a number of things generally accredited to other investigators, emanating as original with the author; reflectors, tongue depressors, nasal dilators, rectangular forceps, and other appliances. Though less apparent in the present edition than before, it is a great pity that a work in the English language should be ever so slightly marred by personal allusions, which detract from its satisfactory perusal, like some of the works of certain continental specialists, who seem to go to more pains to display evidences of their individual ingenuity than to communicate the results of their individual experience. The demand for successive editions of Dr. James' volumes is evidence of their real intrinsic value, and it is to be hoped that subsequent editions of "Sore Throat" and of the "Lessons" will be freed from these painful interpolatory announcements

and intimations, which prejudice the reader unfavorably, and that the "Lessons" will be furnished in future with a table of contents and an index, to render them available for prompt reference. They certainly deserve both.

A Practical Treatise on Surgical Diagnosis; Designed as a Manual for Practitioners and Students. By Ambrose L. Ranney, A.M., M.D., Adjunct Professor of Anatomy and Lecturer on Minor Surgery, in the Medical Department of the University of New York. New York, Wm. Wood & Co., 27 Great Jones st. 1879. pp. 386.

In the fullness of American surgical literature, it is remarkable that no work on surgical diagnosis has until now been produced. We have had the foreshadowing, and even the pre-announcement of a book on the subject, with an authorship that would have been creditable, but it seems to have lapsed into dumb forgetfulness.

The success of the familiar treatise on Medical Diagnosis, by Da Costa, has seemed to point to an open field and a clear track in the surgical domain. But, unfortunately, our practical surgeons who possess the full opportunities for training and experience, and for original observation in surgical diagnosis, are not, or cannot be, book makers; and others, whose control of time and whose culture might incline them to such authorship, would necessarily be merely collaters of the scattered fragments of the literature of the subject, and but repeaters of its well-worn and often erroneous traditions.

This book is hardly what its title claims it to be, "a practical treatise on surgical diagnosis," and its scope and objects would have been better indicated by such a caption as is modestly assumed by the fuller and more comprehensive work of McLeod, which is simply called "Outlines of Surgical Diagnosis." The volume of Dr. Ranney is but the tabulated outlines of surgical diagnosis, and is little more than what might have been styled a dictionary of diagnosis. It is, for the most part, but a compilation of tables of surgical differentiation.

The author says that he has endeavored to produce "a work whose system and arrangement will probably be its chief recommendation." It has been particularly his object to present the symptoms of disease in "marked contrast," and to make it a book of easy reference. The selections in the comparative tables are of such surgical diseases and injuries as are most liable to be confounded. Such selection necessarily requires great discretion, and in this book they are often at fault, from paucity.

It is not difficult to see that this volume is not the outgrowth of the life work and observation of a practical, working surgeon. It lacks the evidence of originality, freshness and thoughtfulness, and only presents the routine and traditional matter and manner of the familiar text books. The plan of its arrangement may have merit, and that might be capable of development, but this work covers but a limited part of the great domain of surgery. The contents are merely diseases of blood vessels, diseases of joints, diseases of bone, dislocations, fractures, diseases of the male genitals, diseases of the abdominal cavity, and diseases of tissues. Many important regions, organs and subjects are unnoticed. The present accurate development of the diagnosis of diseases of the eye, the ear, the nose and the throat are totally ignored.

A fault of the general plan of arrangement in what might be styled tables of differentiation is that it necessitates a vast amount of repetition.

The subjects seem to be very unequally dealt with; of the three hundred and sixty-three pages of the book, exclusive of the table of contents and index, sixty-eight are devoted to the diagnosis of diseases of the male genitals. Under the head of diseases of tissues, the subject of tumors is well tabulated, according to the classification of Mr. T. H. Green, of London, and this is one of the most satisfactory portions of the work.

There are many little points of error which will strike the attention of practical surgeons. Typhlitis is defined to be "an inflammation of the vermiform appendix of the cæcum." In hydrocele of the tunica vaginalis testis the tumor is said to be "*always* translucent." In contrasting femoral hernia with enlarged inguinal glands the latter cannot be said to be "always superficial." Barton's fracture, so called, is not "a condition in which the *styloid process* of the radius and an adjacent portion of the articulating surface are separated from the shaft of the bone." The differential definition of internal and external hemorrhoids, as given, is incorrect.

There may be in this work the creditable basis for a large and really comprehensive book of ready reference in surgical diagnosis, but it falls far short of its general pretensions. Dr. Ranney is capable of more than he has yet attained in this direction, and he has before him the field and scope for a really useful and acceptable production.

R. J. L.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Half-Yearly Compendium of Med. Science,	**2.50**
Reporter and Compendium, - - -	**7.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**8.25**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

NATURAL MINERAL WATERS AS THERAPEUTIC AGENTS.

Natural mineral waters are yearly growing in favor as therapeutic agents. Years ago, when the late Professor Robley Dunglison filled the chair of the Institutes of Medicine at the Jefferson Medical College, that learned and skeptical teacher was accustomed to attribute all or nearly all the benefits derived from such waters to the corrected habits of life, the change of air and scene, the rest from labor or dissipation, and the increased amount of aqueous fluid imbibed, which are the accessories of a residence at "the Springs." Whether his views were correct or not, they have not gained popularity with the profession. Every year, not only are mineral springs frequented by increased numbers of patients, but vast quantities of waters are shipped to distant points and eagerly consumed. Every drug store of any pretence has one or more kinds constantly on draught.

Believing, as we do, that many natural waters are in themselves very efficacious and valuable therapeutic agents, and destined to increase in favor, we cannot but regret that so very little has been done to classify them accurately, to analyze their solid contents and to assign them their proper positions in the materia medica. In this country there is not a single important work on the subject. Nearly all that has been written is to bolster the claims of some particular spring or locality. The numerous descriptive pamphlets sent us every year, from various health resorts throughout the country, are filled with florid statements, defective analyses, and certificates of cure as unblushing and as meaningless as those of the quack medicine almanac.

Our land is not alone in this. A recent writer in a London journal expresses his regret at the part which purely commercial companies are beginning to play in the management of mineral springs. It has been discovered that a spring of water, if it be sufficiently puffed, is a surer and more valuable source of income than a gold mine, and the statements put forward in advertisements are very often absolutely unwarrantable. It is desirable that the profession on both sides of the ocean should unite for the purpose of restraining the statements of those who have merely a money interest in mineral springs, for it will become exceedingly difficult to prescribe this or that water if, by so doing, one should seem to countenance the unwarrantable assertions which are made concerning them. It would be satisfactory if such rash assertions were made only by the trading companies, but this, unfortunately, is not the case, for many of the medical monographs appear to show a very undue amount of local bias, and to lend a too ready credence to startling therapeutic theories. It would be a great boon if the examination of the mineral springs of Europe and the United States could be made by an international commission, which should be entirely without interest in the popularity or earnings of any particular spring.

Until some such measure as this is taken no reliable guide as to the character of this or that spring can be found, and thus one of the most efficient and agreeable of the means of treating disease must remain in a vague and unsatisfactory state.

As the United States is rich in these waters, and offers both a wide variety of them and numerous localities where they occur, it would be an appropriate subject for the consideration of one of those medical or pharmaceutical bodies whose affiliations extend over the whole country, and whose reputation for impartiality is beyond question.

THE VENTILATION OF PUBLIC AND PRIVATE BUILDINGS.

A problem which has long exercised the ingenuity of engineers and sanitary officers, is how to secure pure air in public buildings, with a due regard to the economy of fuel and absence of drafts of cold air. Any one can recall churches, theatres, lecture halls and work rooms where the tainted air has produced headache, sick stomach, vertigo, and even worse results.

An investigation made this spring by Health Officer Dr. Smith Townshend, of the District of Columbia, of the Government buildings in Washington, reveals a neglect of the rudimentary principles of sanitation which is anything but creditable to this country. In that externally magnificent structure, the Treasury Department, he found that the air in all the rooms on the fourth floor, with, perhaps, two exceptions (the engravers' room and wetting room), was unfit for breathing. There is abundant air space in a majority of the rooms, if there was only proper means provided for the removal of the air rendered impure. The great necessity for ventilation which existed here is evidenced by the rude attempts which have been made to accomplish the object. Prominent among these is a series of skylights which open by means of weights and rope pulleys. These were found closed in every instance where a workman was stationed near, and they gave as a reason therefor that draughts were created whenever they were left open. This was always the case in windy weather, and rains or storms necessitated their being closed altogether.

The folly of depending upon windows for ventilation was illustrated many times. The opening of a window occasions a draught of cold air, and the one employed near suffering therefrom is not slow in closing the aperture. Employees being stationed near the windows in every instance, it is impossible to secure any fresh air by this means. Windows are the sole dependence in a majority of rooms in this building. The only salvation of the employees in the rooms of this bureau is the large amount of air space in a majority of the rooms.

The dressing rooms he describes as "perfect pest holes."

The atmosphere of the press rooms was very offensive. These rooms, five in number, have less air space *per capita* than any of the others. The minimum quantity sanctioned by authorities is 500 cubic feet per head where persons are employed at such trades as plate printing, yet here we find but 217 and a fraction air space furnished for each.

In the lower floors, in both rooms and halls, the condition of things is not much better, the air being hot, close and impure.

The secret of the foul air in the halls was found upon getting into the basement, later on. This underground portion of the building is but a vast receptacle for the manufacture of foul air, which, by means of the stairways, is carried into the halls above, and thence distributed via the transoms into the rooms. The hottest air congregating and being held in the upper stories, attracts the air from below, which is always found forcing its way in volumes up the stairways. One need only to walk down one of these openings to have a practical illustration of this fact. The basement is filled with printing offices, binderies, storerooms, and workshops for the various trades, each of which contributes its share of impurity to the air which is sent above to be breathed by the clerks and other employees.

We need not continue to refer to Dr. Townshend's report. We quote it merely to show how, in the most expensive buildings on this continent, the simplest requirements for comfort, health, and effective work have been systematically neglected.

Nor is this neglect confined to public buildings. In most of the costly residences of this and other cities, residences valued from $50,000 to $100,000

each, either the whole matter of ventilation is absolutely overlooked, or the means for securing it absurdly inadequate and foolish.

Yet the principles on which effective ventilation can be secured are not unknown. They have been repeatedly explained and occasionally tested by experiment. Every one knows that the old-fashioned open fireplace, with its fire and current of ascending warm air, is the most perfect of all ventilators. We cannot have open fire places in all rooms, but a ventilating shaft, opening *at the floor* of the room, heated interiorly by a lamp or gas jet, and running to the roof, is just as absolutely efficient and cheap. There is no draught of cold air, no opening of windows, no risk of accumulating carbonic acid gas. This simple principle, properly adapted, is all sufficient for any building.

Notes and Comments.

Therapeutical Notes.

ANTI-RHEUMATIC OINTMENT.

A writer in the *Revue de Thérapeutique* recommends the following in the pains of chronic or subacute rheumatism and gout:—

℞. Gambogiæ,
Myrrhæ,
Canellæ,
Sodii salicylatis, āā ʒ ij
Olei terebinthinæ, q. s. to liquefy.

Sig.—Use with steady friction twice daily, and then cover with wadding.

BELLADONNA IN CHOLERA INFANTUM.

During last summer, Dr. Uhler, of Baltimore, employed belladonna in two cases of cholera infantum, characterized by green stools. The belladonna was employed with the purpose of diminishing the amount of saliva and epithelium, and thus preventing these as far as possible from entering the stomach. Sufficient was given to dilate the pupils. The result was satisfactory, and both patients recovered. Opiates and other remedies had previously been employed without benefit.

PILL FOR CONSTIPATION.

Dr. Foster, of New York, suggests as a remedy for constipation a pill containing—

℞. Rhubarb (Turkey), gr. iij
Carbonate of soda, gr. j
Ipecac, gr. ss
Oil of anise, gtt. v. M.

To the above one or two grains of pil. hydrarg. might be added at times, with benefit. The pills should be taken at night.

DRESSING FOR WOUNDS.

Dr. Q. C. Smith, of California writes to the Nashville *Medical Journal*—

We have quite a number of wounds to treat up here in the mountains, and our favorite plan, especially in head wounds, is to draw the lacerated parts together with silver wire sutures, and keep the parts wet with *paregoric* and thin *simple syrup*, equal parts, leave the wound entirely open to the air and defy bacteriæ, etc. No kind of insect will touch the wound and it rapidly heals—often, in serious cases, without a particle of suppuration.

The Exhibition of Chlorate of Potash in Large Doses in Diphtheria.

The following observation is contributed to the *Southern Medical Record*, by Dr. W. W. Carpenter, of California:—

Potassæ chlorate cannot be borne in sufficient quantity to cure an asthenic case of diphtheria without causing a dangerous, if not fatal, depression of the heart. If combined with quinine or any of its alkaloids, to steady the heart's action, it can be safely borne in larger doses. In fact, the physician who would exhibit it alone is to be pitied. In union with tinct. ferri mur. and quinia, we not only have a much more effective remedy, but a far safer one.

℞. Acidi sulphurosi, ʒ vj
Glycerinæ, ℥ iv
Sol. potassæ chloratis, ad ʒ viij.

Sig.—From one-half to two teaspoonfuls every half hour, according to age.

Small and frequent doses give us all the topical application required.

Coffee in Typhoid Fever.

Dr. Pigne-Dupuytren, in the Pacific *Medical Journal*, claims to cure typhoid fever with coffee. He writes:—

When we say that we cure typhoid fever with coffee we do not pretend to cure by this means a fever which has become complicated by a grave affection of the lungs, by intestinal perforations, or by any accident that happens to cloud the prognosis. In such cases a treatment has to be used which is in conformity with the circumstances. We must admit that since we have had recourse to this plan we have never had to deal with serious complications.

The mode of dispensing the remedy is the following: Give (to an adult) two or three tablespoonfuls of strong black coffee (without chicory)

every two hours, to be alternated with one or two spoonfuls of good claret or Burgundy wine. Make the patient take, in the course of the day, a few wine-glasses of lemonade of citrate of magnesia; then sulphate of quinia.

Results of the Prevention of Conception.

In the last number of the *Vierteljahrschrift für Gerichtliche Medicin*, a physician in Königsberg gives an opinion on the question whether an advertiser who was selling a secret recipe for prevention of conception was guilty of fraud. The means turned out to be vaginal injection with cold water, for which the advertiser sold a special syringe. It was decided that he could not be prosecuted for fraud, but the writer regrets that the existing laws of that country permitted such advertisements.

There is little or no doubt but that this means, whether efficacious or not, frequently leads to uterine disease. It is too much, however, to say, as has been recently maintained, that all measures to prevent conception produce disturbance of the uterine functions. No false notions of possibly bad effects should prevent men from adhering to the rigid truth.

Another Treatment of Sea Sickness.

A steamship surgeon writes to the *Lancet*—

The result of my experience has been to place very great reliance on the following treatment, which I have rarely found to fail:—The exhibition of five grains of bromide of potassium, in pure water only, three times a day, accompanied by a prohibition of all solid food, say for two or three days, limiting the patient in the meantime to a drink of half parts of milk and lime-water. I was induced to try the bromide of potassium from an article I saw about eighteen months ago, in which sea sickness was ascribed to a "series of minute concussions of the brain," which theory has always appeared to me to account fully for every symptom I have noticed present in the malady.

Organic Resistance to a Boiling Temperature.

Ch. Chamberland has found a microscopic organism which lives in nearly all liquid solutions of organic matter, provided that they have been previously neutralized by a solution of potash. It produces germs or spores which, when placed in neutral media, resist a boiling temperature for several hours. A temperature of about 115° (239° Fahr.) kills them very rapidly. His notice is in the *Comptes Rendus*.

Hygienic Effects of Sea and Mountain Air.

An Italian physician, Dr. C. Alberto, says, in a recent work—

The marine air produces the same benefit as that of the mountain, but each has a different *modus efficiendi;* the former acts more forcibly and energetically on the constitution which retains some robustness and internal resources to profit by it, while the second acts more gently, with slower efficacy, being thereby more suitable to the weaker and less excitable organizations. From this important distinction, the conscientious physician, who takes the safety of his patient much to heart, ought to be able to discriminate whether the alpine or the marine atmosphere is the better suited to the case he has before him.

A Case of Sclerostoma Duodenale.

Specimens and a description of a case of this rare parasite are forwarded us by Dr. Walter E. Hendricks, of Martinsville, Ind., through Dr. B. D. Blackstone. The patient is a young man of good habits and in good circumstances. The sclerostoma is common in southern Europe, very frequent in Egypt, but rare in this country. The specimens sent us answer the description of authors, except that they are thicker in proportion to length. Full doses of turpentine are the appropriate treatment. It is sometimes known as the *ankylostomum duodenale*, from the Greek *ankylos*, curved, rounded, and *stoma*, mouth.

Cysticercus in the Eye.

A case of this rare lesion was recently observed in this city. The extraction of the parasite resulted, we hear, in a decided improvement to sight. At a meeting of the Atlanta Academy of Medicine, in March, a case was reported by Dr. Calhoun, particulars of which are given in the May number of the Atlanta *Medical Journal*. In the latter case, on account of the patient's unwillingness and the general bad results of the operation, no interference with the entozoon had been attempted.

Death from Minute Dose of Strychnia.

A student of the laboratory of the Ecole de Pharmacie relates, in the *Union Méd.*, June 3, the fact that a cat belonging to the laboratory died in a few minutes after some convulsions, having eaten a small bird which had been employed in an experiment with strychnia. Still, Prof. Jeanjean had only deposited in the corner of the eye of the bird scarcely a milligram of the acetate of strychnia.

Jaborandi in Obstinate Hiccough.

Dr. Ortille, of Lille, communicates to the *Bull. de Thérapeutique*, May 30, the case of a woman, aged fifty-six, who came under his care for hiccough, which had lasted for seven months. The hiccough was almost continuous, at the rate of thirty or forty times a minute, and was accompanied by vomiting. Occasionally there were intervals of five or ten minutes. Various remedies had been tried in vain, and now a decoction of four grams of the leaves and stalks of jaborandi was prescribed in two doses, to be taken with an interval of a quarter of an hour. The usual sweating and transpiration were produced, as was some vomiting, and in two hours the hiccough had ceased.

Lister's Method in Country Practice.

In his Harveian oration, printed in the Edinburg *Medical Journal*, Dr. H. S. Anderson observes:—

I fear that the chances of success of antiseptic surgery are so small in country practice, that it is apt to be valueless; for I am persuaded that if the system cannot be carried out in the perfect and thorough manner practiced by Lister and others, we are better without it, and must adhere to the old plan of free exposure of the cut surface to the air till the oozing ceases, and then bringing the parts accurately together by stitching with a moderate amount of tension, and keeping the edges quite dry; this is by far the more likely way of getting union by the first intention.

The Rules for Sea Bathing.

The following precepts on this subject were composed by Dr. Dutroleau, on the model of those of the Academy of Salerno:—

"1. Avant le bain tu marcheras,
Pendant un bon petit moment.
2. Puis tu te déshabilleras,
Sans hâte, mais rapidement.
3. Dans l'eau tout de suite entreras,
Sans flâner au bord nullement.
4. Tout d'un coup tu t'y plongeras,
De la tête au pied carrément.
5. Dix minutes y resteras,
Toujours, toujours en mouvement.
6. Enfin, lorsque tu sortiras,
Tu te vétiras chaudement."

—In the June number of the Edinburg *Medical Journal* Prof. Simpson reports a successful case of Battey's operation. The patient was 35 years of age and a sufferer from severe dysmenorrhœa.

Correspondence.

A Case of Extra-uterine Fœtation.

Ed. Med. and Surg. Reporter:—

On February 11th, 1879, at 10 A.M., I was asked by Dr. Weir, of Agency City, to visit a "singular case," which he (Dr. Weir) had the day before, for the first time, seen with Dr. La Force, of that town.

The case was said to be labor at the eighth month of gestation, with puerperal convulsions, and an inability to discover by touch any os uteri. The woman, Mrs. C., had had two children previously without any unusual trouble. Dr. La Force, the attendant physician, was out of town, and Dr. Weir was not acquainted with the previous history of the case.

I found her unconscious, unable to speak, restless and rolling about on the bed, evidently suffering severe pain; had not had a convulsion for several hours; had had several since 3 A.M. of the 10th, when, as was said, labor pains had commenced. Her husband had died a few weeks previously. Her sisters (who had been with her) were not present; so there was no one to give any history of the case. I found, on examination per vaginam, a large, firm, rounded mass in the upper portion of the vagina, feeling like some portion of soft parts of the body felt through the uterine walls; after a few moments a clouded vision by touch. There was high up, to the left, and above the tumor in the vagina, an os and cervix uteri, which I said then was about as large as a three months' pregnancy would occasion.

By an external examination of the abdomen, I discovered an irregular enlargement, a round, hard tumor, in the left iliac region, extending in a less rounded surface diagonally to the right hypochondriac region. I diagnosed an extra-uterine fœtation, advised morphia hypodermically, sufficient to quiet, and asked the privilege of a post-mortem soon after death.

She died on the morning of the 13th. I made a post-mortem at 4 P.M.; present, Drs. Weir, La Force and Ball, of Agency City; and Dr. A. O. Williams, of Ottumwa. We found a fœtus apparently very near full term, occupying the abdominal cavity, presenting the back toward the abdominal walls of the mother, the breech in the right hypochondriac region, arms and legs folded inwardly, the head in the left iliac, underneath the uterus, which was enlarged, so that it would weigh about eight ounces. The placenta was located low, and was the presenting part felt on examination by touch. The post-mortem proved in every particular my previously expressed opinion of the condition and position.

I have since learned that on the 12th, the day after my diagnosis was expressed, the woman became conscious, and recognized and talked with her sisters. Dr. La Force has informed me that during the preceding seven or eight months he had been frequently called to prevent threatened abortion and miscarriage, and to relieve acute abdominal pain, vomiting, nausea, etc., having been constant, and several times a discharge of water, like the rupture of membranes, which he supposed it was, but that he had never

made any vaginal examination but once, and then when she supposed herself three months pregnant.

Had the case been properly diagnosed a month earlier, would not abdominal section have been justifiable? S. B. THRALL, M.D.

Ottumwa, Iowa, May 11th, 1879.

Aphonia in Typhoid Fever.

ED. MED. AND SURG. REPORTER:—

In three fatal cases of typhoid fever, all females, married, and mothers, each, of several children, I have observed a symptom which I do not recollect to have seen mentioned in books or clinical lectures.

The first was a woman, about thirty years of age, sick with a mild attack of the fever, who was noticed during the early morning of the sixth day to be completely aphonic, not able to utter the slightest whisper, and who died during the morning of the seventh day.

The second case was about twenty-five years of age, with a severe form of the fever. She became aphonic during the last of the second week, in the latter part of the night, and died in about thirty hours, during the morning.

The third case was about thirty years of age, who became aphonic during the early morning of the twenty-seventh day of her sickness, and died during the morning of the twenty-eighth day.

There had been no marked delirium in either case; deglutition during the aphonia, although impaired, was possible with fluids, in each case. Intelligence during the aphonia was fair in each, as evinced by the general expression of the face and eyes, and by the latter intelligently following the motions of persons in the room. The aphonia was sudden with each, neither appearing any worse than for a day or two before, and it came on during the early morning, and was followed by death the next morning. It was complete in each, not the slightest sound being possible from the lips of either. The decubitus was dorsal with each during the whole time of the aphonia, and from its onset till death, which was sudden; there were none of the usual evidences of dissolution.

If anything like the above is mentioned in books, I shall be glad to receive the reference.

Fairfield, Texas. J. J. BONNER, M.D.

The Diagnosis of Rectal Diseases.

ED. MED. AND SURG. REPORTER:—

In July, 1876, a Mr. E., aged thirty, of nervous temperament, came into my office for some ointment for his piles. Upon questioning him, he said that they had troubled him for two years, sometimes only just slightly, then again so badly that he would have one or two epileptoid convulsions a week, then go some time without a convulsion. I also learned that he had been treated by three of our regular practitioners, with only varying success. So it occurred to me that I had better make an ocular examination, and see just what was the trouble. Imagine my surprise to find no pile, but a slight fissure of the rectum. I then introduced my finger into the rectum, to see if there were any internal piles. But I could find none. I told him that when he got cured of his fissure, I thought he would also get cured of his fits, as he called them, and such has been the case.

I ruptured the sphincter in the manner described by Dr. Rush, in the REPORTER for June, 14th, 1879, page 526. The after treatment was simply tonics. It is now almost three years since the operation, and he has had no trouble from either his piles or his fits since.

I write this to show how important, in all diseases of the rectum, to make a careful ocular and digital examination. The gentlemen who had treated the case had taken his word that he had piles, instead of looking for themselves.

E. W. HILL, M.D.

Glens Falls, June 16th, 1879.

Local Treatment of Phimosis.

ED. MED. AND SURG. REPORTER:—

In the February number of the year 1875 I reported to the Cincinnati *Lancet and Observer* (now *Lancet and Clinic*) a case of *Paraphimosis*, with conservatory treatment.

I now report in brief a statement of my local treatment of a case of *phimosis*, this case being a boy of about the same age (three years). The little prowler would run to meet his little sister when on her homeward way from school through a wet bottom, during the cold changes of March last, and on many other occasions would steal out from the dwelling house to play with his little brother and sister, which he seemed to do with impunity until March 16th. On this day I was passing a road near by when called to see him. I found the following symptoms present: Partial paralysis of the inferior extremities, his legs being drawn up to his abdomen, irritable temper, which was unusual with him, flushed face, had not voided urine for about twenty-four hours. My attention was called by his parent to his genital organ, where I found the prepuce contracted and so lengthened that its measure exceeded that of the penis. It was with much difficulty that we brought to view the meatus, and when seen it was of a dark brown, almost dark enough for melanosis; priapism of the organ was also observed, which continued until our application had been used for some hours, as we thought the priapism was an important factor. We made scissions through muslin cloths, so as to make a ring to surround the penis to its head; these cloths we dipped in the coldest of well water, and reapplied in quick succession, and when the morbid erection had been subdued by these cold local applications, I then used Dr. Josiah C. Nott's India rubber bag, stop cork and nozzle (to be used with his double catheter), by gathering up the foreskin and holding it in juxtaposition to the glans penis, pointing at above the meatus (and confining the water with which it had been charged). to the mucous surfaces of the prepuce and penis by forming a ring with my thumb and finger around the elongated prepuce, pressing it close to the nozzle while I injected the warm water

with the other hand, until I completely dilated the foreskin and washed away the irritating secretions, upon the withdrawal of the nozzle. Conjointly with the local treatment I gave, in frequent and large doses, the fluid extract hydrangea, as a lithotriptic and cathartic, from the beginning of the treatmeut. The boy was playing the next day. L. A. DAVIDSON, M.D.

West Milford, West Virginia.

NEWS AND MISCELLANY.

Sixth International Medical Congress.

The sixth congress is to be held at Amsterdam, from September 7th to 13th, inclusive. Prof. Donders is the President of the Committee of Organization, and Dr. Guye, of Amsterdam (to whom all communications respecting the Congress are to be addressed), is the Secretary. The French language is to be employed at the general meetings of the Congress, and either French or German at the meetings of sections; but members will be allowed to use other languages, and their addresses may then be translated into French.

Officers of the Ohio State Medical Society.

The following officers were elected at the annual meeting at Dayton, June 7th:—

President—Dr. J. A. Murphy, Cincinnati.

Vice Presidents—Dr. John Davis, Dayton; Dr. Thomas McEbright, Akron; Dr. J. D. Edwards, Xenia; Dr. C. A. Kirkley, Toledo.

Treasurer and Librarian—Dr. T. W. Jones, of Columbus.

Secretary—Dr. J. F. Baldwin, of Columbus.

Assistant Secretary—Jesse Snodgrass, Dayton.

The meeting was well attended, and in all respects a satisfactory one.

Quinine on the Free List.

The following is the full text of the "McKenzie quinine bill," which passed the Senate and became a law on the first of July:—

"A bill to put salts of quinine and sulphate of quinine on the free list. Be it enacted, etc., That from and after the passage of this act the importation of salts of quinine and sulphate of quinine shall be exempt from customs duties, and all laws inconsistent herewith are hereby repealed."

The manufacturers of this city, Powers & Weightman, and Rosengarten & Sons, are said, in the daily papers, to be preparing to close their quinine departments, as the duty on East Indian cinchona bark, which is ten per cent., and the heavy Government tax on alcohol, render it impossible for them to compete with foreign manufacturers of the article. In this event the American profession and their patients will be at the mercy of the French and English quinine makers, and of the drug brokers of New York and London. We shall be surprised if there is not a clamor before long, either to have the duty restored on quinine, or else to have the cinchona bark and the alcohol used in extracting its alkaloid rendered free.

Native Chinese Medicine.

Dr. Keating, of this city, who accompanied General Grant during his Chinese tour, in a conversation on Chinese hospitals remarked:—

"On numbers of the patients I observed little blue spots, and I thought I was about to learn of some peculiar disease. Upon inquiry, however, I found that they were caused by the Chinese mode of treating internal inflammation. The poor follows who bore the blue marks had been treated for sore throat, by having the skin of their necks taken by the physician between thumb and forefinger and screwed around."

This reminds us that several years ago, Dr. Jameson, of Shanghai, when writing on the subject of obstetric medicine among the Chinese, published some statistics to prove that in a Chinese woman the physiological processes of utero-gestation and parturition are so closely surrounded by the dangers arising from no-management and mismanagement that pregnancy becomes a pathological condition but one-half less formidable than typhus fever, in England.

New Pharmaceuticals.

WARNER'S PILL. QUINIÆ SULPH., SUGAR-COATED.

Messrs. Wm. R. Warner & Co., of this city, are justly celebrated for the uniformity and excellence of their sugar-coated pills. We have recently been trying their quinine pills thus prepared, and they are certainly as easy to swallow, as efficient and as neatly prepared, as any we have ever seen. None but the purest sulphate is used.

W. H. SCHIEFFELIN & CO.'S SOLUBLE PILLS.

Among the pharmaceutical preparations of the day the "soluble-coated pills and granules" of W. H. Schieffelin & Co., of New York City, deserve a high position. The coating is an inert soluble compound, dissolving upon the tongue in all cases within thirty seconds, entirely tasteless, perfectly transparent and colorless, thus disclosing to the eye the exact color and appearance of the pill-masses. We have examined a number of varieties and can recommend them.

JAMES HORLICK'S PREPARATIONS.

Horlick's "Food for Infants" and "Granular Sugar of Malt," are two productions of the laboratory which will recommend themselves, wherever they are once introduced. The Food is very palatable, perfectly soluble, and not farinaceous; the Sugar of Malt has a delicious flavor, and is eminently suited for the dietetics of the sick room and nursery.

Personal.

—Dr. A. A. Smith has been appointed Professor of Materia Medica in Bellevue Hospital Medical College, N. Y., in place of Dr. Polk, resigned; and Dr. Joseph W. Howe has been appointed Professor of Clinical Surgery in the same school.

Alexis St. Martin.

From a recent letter to Dr. B. V. Hoagland, of West Union Ohio, we learn that Alexis St. Martin, famous in physiological works for the experiments of Dr. Beaumont Martin, is still alive, and at present a resident of St. Thomas, Joliette county, Province of Quebec, Canada, and is seventy-eight years old. The wound in his stomach has never closed, and at present the opening in his side is nearly an inch in diameter. His general health appears not to have been in any way affected by the curious wound in his side, but has always been excellent. For his age he is now quite strong and hearty. He has been the father of twenty or more children, of whom four are now living. Has always been a hard worker, and never suffered from lack of digestion.

Items.

—It is rumored that Dr. B. W. Richardson has been offered £5000 for a lecturing tour in the United States.

—The Michigan *Medical News* writes in despair as to introducing the metric system to the present generation of physicians.

—The Russian Society of Hygiene propose to print school books in white letters on a black ground, in order to check the increase of myopia in scholars.

—The Baltimore Academy of Medicine has offered $100 for the best essay on a medical subject, to be written by a physician residing in the State of Maryland. For particulars, address Dr. B. B. Browne, 304 Madison Av., Baltimore.

—The danger of transmitting disease by books has been investigated by the Chicago Public Library directors. They have corresponded with physicians and librarians in various parts of the country, but not one has ever known of a case of contagious disease having been imparted by a book from a circulating library.

OBITUARY NOTICES.

—Samuel Dellenbaugh, M.D., one of Buffalo's most highly respected citizens, died suddenly lately. He was seventy-three years old.

—The well-known London Dermatologist, Dr. Tilbury Fox, died last month, at the early age of 43 years. He was a hard worker and fertile writer, best known in this country for his "Epitome of Skin Diseases" and "Atlas of Skin Diseases." His death was from aortic disease, supposed to be consequent on rheumatic fever, acquired in a journey in the East in 1864.

—Early in June Prof. Piorry, of Paris, died, at the advanced age of eighty-five. His professional and literary career has indeed been an active one during the last half century, and until a month or two of his death he was one of the most assiduous members of the Academy of Medicine, taking part in some of its debates recently with all his pristine vigor. He was formerly Professor of Internal Pathology, and then of Clinical Medicine, and his communications to journals and learned societies have been very numerous. Among his works are his well-known "System of Medicine," containing his original and fanciful nomenclature of disease, and his celebrated "Traité de la Percussion Médiate, ou du Plessimetrisme."

QUERIES AND REPLIES.

To E. S., of Florida.—I have never adapted the method of treatment spoken of in my last two articles to either prostatorrhœa or spermatorrhœa. I should hardly think the current would be strong enough. But have seen good results from the use of the galvanic current from a battery in the treatment of the above-mentioned diseases. Should be used by sittings of from one-half to one hour twice a day.

O. E. Herrick, M.D.

Dr. B. F., of Cal.—The physician who was sent by your friend to see your wife, should, of course, have his traveling expenses paid by you, although he did come too late. You are the person obliged.

Dr. H. V. R., of Ga.—You will find a brief description of the uses of compressed and rarefied air, with numerous references to other authors, in Cohen's volume on "Inhalation."

Dr. J. K., of Missouri.—As other remedies in your case of urticaria have failed, we may mention that Dr. A. M. Lyles (*American Practitioner*, May, 1871) has found that ten drops of nitro-muriatic acid in a wineglassful of water, one hour before eating, is an almost unfailing remedy for urticaria.

Linum.—Quite a number of cases have been reported from time to time, where linseed poultices have brought about inflammations of the skin, and, apparently by metastasis, swelling and congestion of the mucous membranes.

MARRIAGES.

BABCOCK—WESTON.—At Montclair, N. J., on Thursday, June 12th, at 12 o'clock, by the Rev A. H. Bradford, Robert H. Babcock, M.D., of Kalamazoo, Mich., and Lizzie Clinton, daughter of the late M. L. Weston.

BECKER—WATSON.—In New York city, on Tuesday, June 17th, at the residence of the bride's brother, Henry Shelton, Esq., by the Rev. Lea Luquer, George Ferdinand Becker, of Berkeley, Cal., and Alice Theodora, daughter of Dr. A. T. Watson, of Dresden, Saxony.

BROWN—GARCELON.—At Wayne, Me., June 1st, by Rev. S. Hooper, Charles W. Brown, M.D., of Dexter, Me., and Miss Alice Garcelon, daughter of Esquire Garcelon, of Livermore Falls, Me.

BRUNER—GIBBONEY.—In Duncansville, Blair county Pa., June 19th, by Rev. William J. Gibson, D.D., William S. Bruner, M.D., and Clarinda L. Gibboney.

CHEESEMAN—PEALE.—In Cincinnati, O., at the residence of the bride's mother, 416 Court street, June 3d, by Rev. A. M. Worcester, Dr. John C. Cheeseman, of Kelley's Station, Pa., and Miss Sallie A. Peale.

DICKINSON—WALTON.—On June 19th, by Rev. W. C. Alexander, Dr. J. T. Dickinson, of Parkesburg, and Joen B. Walton, of Cochranville, Pa.

FISHER—SHOTT.—In this city, June 19th, at their residence, 1043 Fairmount avenue, by F. L. Magoon, D.D., J. F. Fisher, M.D., and M. Jennie Shott, both of Philadelphia.

DEATHS.

MARTIN.—At his residence in Xenia, Ohio, on the 21st ult., Dr. Samuel Martin, in the 83d year of his age.

TAMAR INDIEN,

A laxative, refreshing, and medicated Fruit Lozenge, agreeable to take, and never causing irritation. Its physiological action assures the immediate relief and effectual cure of

CONSTIPATION, CEREBRAL CONGESTION, HEADACHE, INDIGESTION, BILE, HEMORRHOIDS, etc., etc., by augmenting the peristaltic movement of the intestines, without producing undue secretion of the liquids. Unlike pills and the usual purgatives, it does not predispose to intestinal sluggishness, and the same dose always produces the same effect, that is to say, never needs increasing. These properties render "Tamar" invaluable to the weak and debilitated, and especially to ladies previous and subsequent to their accouchement. It is recommended by the most eminent Physicians of Paris; notably Drs. BELIN and TARDIEU, who prescribe it constantly for the above complaints, and with most marked success.

Prepared by **E. GRILLON,** Pharmacien de lère classe, 27 Rue Rambuteau, Paris. To be had of all respectable Chemists throughout the world.

PEPTODYN.

The New Digestive is a combination of the whole of the Digestive Secretions—Pepsine, Pancreatine, Diastase, etc.,

Forming an invaluable remedy in the treatment of all forms of Dyspepsia, and diseases arising from imperfect nutrition.

N. B.—*The success of this Remedy has led to several imitations of it,* which consist largely of Milk Sugar, and, as compared with Peptodyn, are of little or no real value as digestive agents.

SAVORY & MOORE, 143 New Bond Street, London.

PARIS, 1867. Prize Medal.

1868. Silver Medal.

1872. Gold Medal.

1873, VIENNA. Medal of Merit.

BOUDAULT'S PEPSINE

IN POWDER, also WINE, ELIXIR, SYRUP, PILLS, AND LOZENGES OF PEPSINE.

Since the introduction of Pepsine by Boudault in 1854, **BOUDAULT'S PEPSINE HAS BEEN, AND IS STILL CONSIDERED, THE MOST RELIABLE,** as is attested by the awards it has received at the Exhibitions of 1867, 1868, 1872, 1873, and in 1876 at the Centennial Exposition in Philadelphia.

IT IS THE ONLY PEPSINE USED IN THE PARIS HOSPITALS.

Careful tests will enable any one to satisfy himself that **BOUDAULT'S PEPSINE HAS A DIGESTIVE POWER AT LEAST DOUBLE** that of the best Pepsines in the market, and that it is really the cheapest.

It is Sold in 1 ounce, 8 ounce, and 16 ounce Bottles.

Beware of so-called French Pepsines bearing fictitious names, and prescribe Boudault's only.

BLANCARD'S PILLS

OF UNCHANGEABLE IODIDE OF IRON.

Blancard's Pills of Iodide of Iron are so scrupulously prepared, and so well made, that none other have acquired a so well deserved favor among physicians and pharmaceutists. Each pill, containing one grain of proto-iodide of iron, is covered with finely pulverized iron, and covered with balsam of tolu. Dose, two to six pills a day. The genuine have a *reactive silver seal* attached to the lower part of the cork, and a green label on the wrapper, bearing the fac-simile of the signature of

Blancard

Pharmacien, No. 40 Rue Bonaparte, Paris.

without which none are genuine.

BEWARE OF IMITATIONS.

E. FOUCERA & CO., Agents,

NEW YORK.

PHOSPHOROLE.

PHOSPHORUS and COD-LIVER OIL

have now an established position throughout the civilized world as important therapeutical agents. A *perfect combination* of the two has long been a desideratum, since they are both of value in the same disorders, while the cases in which one is demanded and the other contra-indicated are exceedingly rare.

The combination in PHOSPHOROLE has the twofold advantage of furnishing *the best possible form* for the administration of *phosphorus*, and *a more effective form* for the administration of *cod-liver oil*.

With regard to the former, it has been decided by the highest chemical and medical authorities that *phosphorus* should be administered *in a free state*, and in a vehicle which ensures its *perfect diffusion*, its *absolute unalterability*, and, as far as possible, its *prompt assimilation* without the gastric irritation to which the ordinary methods of exhibiting the agent give rise. It is well known that pills, emulsions, solutions in ether, chloroform, vegetable oils and resin, etc., have all failed to fulfill one or more of these conditions. Even an ordinary solution of phosphorus in cod-liver oil would not answer the purpose in all respects. We claim, however, that PHOSPHOROLE completely satisfies all the conditions. From the method of preparing it, in an atmosphere of dry carbonic acid, the phosphorus is *entirely dissolved without oxidation*, and by our mode of manipulation *a positive uniformity of strength* is ensured. It is then promptly bottled and sealed, and its *stability and permanence* thus secured. The exact amount of phosphorus in each dose is known, its efficiency is ensured, and the irritant effects upon the stomach are reduced to a minimum by the blandness of the oil. As a means then of administering *phosphorus* in the many cases in which it is indicated as a *nervous tonic and stimulant*, it is claimed that PHOSPHOROLE is the best attainable in the present state of our knowledge.

The value of *cod-liver oil* in phthisis is so familiar to the physician that it is needless to dwell upon it. But the value of *phosphorus* is also universally recognized in this disease, especially when complicated with nervous derangements. The *combination* of the two therefore furnishes a more effective form for the administration of cod-liver oil in the great majority of cases in which that remedy is indicated, and one which will at once commend itself to the profession.

A dose of two teaspoonfuls of PHOSPHOROLE contains $\frac{1}{100}$ of a grain of phosphorus. This dose, when given after a meal, is effective, and not very liable to interfere with digestion. *Phosphorus is cumulative in its action, and should be administered with watchful care.* About $\frac{1}{12}$ grain is considered the largest safe dose, and we rarely need go higher than $\frac{1}{20}$ or $\frac{1}{30}$ of a grain. At the very first appearance of the smallest gastric derangement, the exhibition of phosphorus should be stopped.

PHOSPHOROLE is handsomely put up in pint bottles only, and may be obtained at all first-class druggists throughout the United States.

Descriptive Circulars furnished upon application.

Correspondence with Physicians solicited.

W. H. SCHIEFFELIN & CO.'S
SOLUBLE
Pills and Granules.
UNEQUALED FOR
Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

1. The best materials are used in their manufacture.
2. No article required by a formula is omitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.

Our list of Pills and Granules embraces those made according to the formulæ of the U. S. Pharmacopœia; also most of those in common use among the profession.

Trade supplied in Philadelphia by

1164–1215eow ROBERT SHOEMAKER & CO.

R. & J. BECK,
MANUFACTURING OPTICIANS,
1016 CHESTNUT STREET,
PHILADELPHIA,

Beg to call the attention of physicians and students to the following novelties recently introduced by them:—

Beck's New National Microscope, Monocular,	$ 75.00
Beck's New National Microscope, Binocular,	100.00
Beck's Economic Microscope, Monocular,	35.00
Beck's Improved Economic Microscope, Monocular,	50.00
Beck's Improved Economic Microscope, Binocular,	80.00
Beck's New Histological and Dissecting Microscope,	25.00
Beck's New Model Dissecting Microscope,	15.00
Beck's New Volute Turn Table, self-centering for all slides,	7.00
Mr. Walmsley's New Freezing Microtome, complete, with Atomizer,	20.00
Beck's New Clinical Thermometers, with indestructible index and ineffaceable scale.	
Dr. Seiler's Section Knife and Carrier,	12.00
Dr. Woodward's Diatom Prism, mounted,	1.50

The above instruments, together with every article used by the microscopist, will be found fully illustrated and described in our catalogue of 144 pages; mailed free to any address.

WOMAN'S HOSPITAL MEDICAL COLLEGE
337 and 339 S. Lincoln St., Chicago.

The *Tenth Annual Course of Lectures* will commence the first Tuesday in October, 1879, and continue twenty-one weeks, The Spring Term will commence April 1st, and continue twelve weeks. College building new. Clinical and Dissecting advantages unsurpassed.

FACULTY.—William H. Byford, A.M., M.D., President, Obstetrics; T. D. Fitch, M.D., Secretary, Gynecology; Charles W. Earle, M.D., Treasurer, Diseases of Children; I. N. Danforth, M.D., Pathology; J. E. Owens, M.D., Surgery; Henry M. Lyman, A.M., M. D., Practice of Medicine; D. R. Brower, M.D., Therapeutics and Nervous Diseases; Sarah H. Stevenson, M. D., Corresponding Secretary, Physiology; D. W. Graham, A.M., M.D., Anatomy; Plymouth S. Hayes, M.D., Chemistry.

For information or announcement, address either of the Secretaries, at 125 State Street.

1141–1192 W. H. BYFORD, A.M., M.D., *President.*

Sunnyside Medical Retreat
For Mental and Nervous Diseases, Inebriety and the Opium Habit,
FORT WASHINGTON, NEW YORK CITY.

This home, situated on the banks of the Hudson, under the management of Dr. Edward C. Mann, late Medical Superintendent of the New York State Emigrant Insane Asylum, receives cases of either sex affected with mental disorders, Inebriety or the Opium habit. The beauty of location and surroundings, handsomely furnished apartments, and the attentions and comforts of home life, all combine to make Sunnyside an attractive and popular private retreat. Applications may be made to Dr. Mann, either by mail or personally, at Fort Washington. Twelve trains daily from Hudson River Depot, 30th St., and 10th Ave. Broadway and 23d St. line of stages run direct to depot. The profession respectfully invited to call, and cordially welcomed. 1152-1y

Lectures on Experimental Physiology.

Delivered in the Physiological Laboratory of the University of Pennsylvania,

BY ROBERT MEADE SMITH, M.D.,

Demonstrator of Experimental Physiology.

(Reported for the Medical and Surgical Reporter.)

Lecture VI.—Pancreatic Digestion.

(*Continued from Vol.* XL, *page* 512).

Passing over the secretion of Brunner's glands, concerning the functions of which there is little known, we have to-day to study the secretion of the pancreas. The pancreatic fluid is poured into the small intestine immediately after the entrance of the bile, or in some instances simultaneously with it and the secretion of Brunner's glands. While the pancreas is one of the most constant of all the glands, existing in all mammals, in birds, reptiles, and in most fish and insects, its anatomical form is subject to great variation in different animals; it will be only necessary for our present purpose, however, to describe the arrangement in those animals which are ordinarily suitable for operation, for I need hardly tell you that here, as in the study of the other digestive fluids, we make use of fistulæ for the purpose of collecting this juice. In the dog, the animal almost invariably selected for this operation, the pancreas is found in the same situation as in mammals, birds and reptiles, viz., in the concavity of the constantly present curvature of the duodenum. In the dog, as in other mammals in which the duodenal mesentery is short or absent, this gland is compact, elongated and bi-lobed, one portion extending horizontally, toward the spleen, with the other portion descending at a right angle parallel to the duodenum. At the angle the pancreas is closely adherent to the duodenum, and even overlaps it, being connected by a multitude of small blood vessels, while the descending portion lies free in the abdominal cavity. There are in the dog, as in most mammals, two pancreatic ducts, the upper and smaller one opening into the duodenum in the same papilla as the biliary duct, while the larger and principal duct opens into the duodenum about two centimeters lower down. These ducts communicate by frequent anastomoses, but it is the lower one alone which is invariably selected in the operation. In those animals in which the duodenum has a wide mesentery, as in the rodents, the pancreas forms an arborescent mass between the two layers of the mesentery. This is the plan of arrangement in the rabbit, and also in the cat. In the rabbit the pancreas has two ducts, but the upper one, which enters the duodenum with the biliary duct, is very small, while the lower one is very long and enters the intestine about 30–40 centimeters below the pylorus, thus offering an arrangement suitable for operation. In the cat the arrangement of these ducts is so irregular as to baffle all description; in most cases there are many of them, and sometimes, as occurs quite constantly in the seal, the principal duct dilates into a sort of reservoir before entering the intestine.

Pancreatic fistulæ may be either temporary or permanent, but as the method of operating in each is not identical, I will describe them separately.

For the making of a temporary fistula, a large dog, preferably a sheep dog, is to be selected, as one which will offer the greatest probability of

escaping peritonitis, a result which would be disastrous to the success of the operation, since the pancreas is extremely susceptible to inflammation, and as a consequence the secretion becomes perverted and its properties cannot be rationally studied.

The operation is itself quite a difficult one, principally from the difficulty of finding the duct without injuring the gland or its numerous blood vessels, and requires a perfect acquaintance with the anatomy of this region and a considerable amount of operative skill. I would, therefore, advise any of you who wish to perform this operation to dissect the parts first on a dead animal. To be thoroughly successful the operation should be performed as rapidly as possible, so as to avoid exposing the parts any longer than necessary, while the pancreas itself should be handled with the greatest gentleness; and should be performed without an anæsthetic, so as to avoid subsequent vomiting and possible vitiation of the secretion.

The object of this course, however, is not only to demonstrate to you physiological facts, but also to teach you to operate for yourselves, so I will, therefore, perform this operation before you, on an anæsthetized animal, and so slowly as to permit each of you following every step of the operation, though the success of the operation, as regards the character of the secretion, will be probably thereby interfered with.

Two hours ago this dog received a hearty meal of bread and meat, and now that he is etherized and fastened on his left side, the belly being shaved, I will make an incision in the right hypochondrium, extending downward from the end of the last false rib, about five centimeters, and parallel with the linea alba, every bleeding point being tied before the abdomen is opened, and the peritoneum divided on a director.

Passing the index and middle finger of my left hand into the wound, the duodenum is easily recognized; the fingers are then carried well down into the right hypochondrium, to the right and then back of the convex surface of the arch of the duodenum, and then, keeping their palmar surface directed upward, the fingers are carried behind the duodenum and pancreas, which are then both to be drawn together out of the wound. The animal being in full digestion, the tissue of this organ is of a rosy pink coloration. By this manipulation the parts preserve their normal relation and the anterior surface of the pancreas presents in the wound. The next step, and perhaps the most difficult, is the finding of the duct, a proceeding rendered difficult, not only by the extreme shortness of the duct, but by its being surrounded by numerous blood vessels which bleed very easily, and which bridge over the furrow between the duodenum and overlapping edge of the pancreas. By keeping the anterior surface directed forward, this difficulty is reduced to a minimum, since here the duct is nearer the surface, and is only surrounded by a few small vessels, while on the posterior surface the vessels are very large, and it is just back of this lower large bundle of vessels that the duct enters the intestine. Now, on carefully pushing aside with a blunt hook the overlapping edge of the pancreas at the lower border of the angle formed by the transverse and vertical portions of this gland, and about two centimeters below the ductus choledochus, the larger pancreatic duct is seen, and may be distinguished from the blood vessels by its larger size and whiter color. I will now pass a thread around the duct, open it with a pair of fine scissors, and insert a small silver canula, about five mm. in diameter, and about ten cm. long, pushing it in up to the first division of the duct. I will now tie it securely in by the thread which I passed around the duct, and to make it still more firm I will pass a stitch through the serous coat of the intestinal wall, and fasten the canula there also.

The duodenum and pancreas are then returned to the abdominal cavity, retaining the ends of the thread and the free end of the canula in the wound, which is then closed by sutures, first sewing together the muscles and then the skin. Now, upon withdrawing the stylet from the canula, a few drops of a colorless, limpid fluid escape, which flow more rapidly when the animal makes any movement, and which is strongly alkaline. I will now fasten a rubber bulb, furnished with a stop cock, to the canula, to collect the juice. I will first compress the bulb, so as to empty it of air, and then, on closing the stop cock, the tendency of the bulb to expand draws the fluid out from the ducts. Generally the fluid is secreted quite rapidly and may be collected for several hours; after the first day, however, the character of the secretion alters, and is no longer normal and suitable for study. If it does not flow rapidly it may be stimulated by injecting ether through a tube into the stomach; vomiting stops the secretion. Usually after the second day the tube and threads drop out, or else they may be gently removed, and the wound generally heals readily, and as the duct becomes restored, the same animal may again be used for the same purpose.

One difficulty we have to contend with in this operation is, that since the duct is so short the canula is very apt to slip out; this may be partially remedied by having a canula made with a little bulb on the end to be inserted, or a T-shaped canula may be used, the duodenal end of which must, of course, be closed. If such a canula is used, it is better to have one made in two sections, one being first inserted in the duct and the other, which is to come out of the wound, screwed in afterward.

The method of operation which you have just seen me employ is essentially that first devised by Bernard, and he always held that permanent pancreatic fistulæ were unreliable. By a somewhat different method of operating, however, Ludwig and Bernstein have succeeded in establishing permanent pancreatic fistulæ, which yield a comparatively normal secretion, though even here it differs somewhat from the fluid obtained by temporary fistulæ. I have here a dog in which ten days ago I established a permanent fistula after Ludwig and Bernstein's method. I selected a small dog for this operation, as in them the pancreas is nearer the middle line than in large dogs, and hence the parts are not as much disturbed by the fistula. The dog having been kept fasting for twenty-four hours, so that the pancreatic vessels should contain as little blood as possible, after narcotizing him by a subcutaneous injection of morphia, I opened the abdomen by an incision about two centimeters long, made in the linea alba and midway between the xiphoid cartilage and the umbilicus. The duodenum and pancreas were then drawn out of the wound, and the pancreatic duct isolated and opened by a little cut in one side. Instead, then, of inserting a canula, two pieces of lead wire, bent at a right angle, were introduced, one wire being passed toward the gland, and the other into the intestines; the remaining halves of each wire were then twisted together so as to form a T-shaped piece, the middle limb of which projects through the wound. Owing to this shape of the wires they cannot fall out and cannot move around in the duct, and since wire was selected which would not fill up the calibre of the duct, the flow of the secretion into the intestine is not interfered with. After the insertion of the wire I passed three stitches through the wall of the intestine near the duct, and then returned the duodenum and gland to the abdominal cavity, taking care to keep the ends of the wires and threads in the wound. The threads were then used as sutures to close the wound, and at the same time to keep the duodenum in apposition with the abdominal walls. The next day, when inflammatory adhesion had probably taken place, the stitches were taken out, but the wire left in, and in three or four days more the juice was collected and examined. You see that the wound has now almost entirely healed, with the exception of a little fistulous tract at the sides of the twisted wires, from which the juice is exuding. The fistula might be preserved even after removal of the wires, but would require the daily passage of a fine elastic probe.

I will now collect some pancreatic fluid from this fistula. I have here a wooden support, consisting of four upright bars, joined at the top by transverse pieces from which a horizontal bar is suspended by a cord and pulleys. I will fasten the dog to this horizontal bar by two straps, which pass under his belly, and then raise the horizontal support until the dog can barely touch the table with his toes. Thus suspended, he remains perfectly motionless, and by fastening a small funnel over the fistula, the juice may be collected in a glass below.

We are now prepared to examine the physical properties and composition of the pancreatic juice, and for that purpose I will make use of a fluid which I have been collecting for the last few hours from a recent temporary fistula. Three hours and a half ago I made a temporary pancreatic fistula on a large dog, which was in full digestion, and without employing any anæsthetic. The operation from first to last only occupied seven minutes, and nothing occurred which could interfere with the normal character of the secretion. I will now open the stop cock, and on compressing the bulb I am able to collect 20 cc. of fluid. It is a clear, colorless, viscid liquid, of a strongly alkaline reaction; morphologically it contains few or no structural elements, though corpuscles similar to those found in saliva have been claimed by Kühne to exist, and occasionally free particles of oil. Chemically its composition is complex, and not yet thoroughly established; it differs from the other digestive fluids in containing an exceptionally large amount of proteid, varying, however, with the rate of secretion, the increase of solids not bearing a proportionate increase to that of the fluid elements. The amount of solids also varies in the fluid obtained from temporary and permanent fistulæ, in the former being from 8–10 per cent. (Bernard), and in the latter 2–5 per cent. (Bernstein). Fresh normal pancreatic juice contains albumen, alkali-albuminate (casein), a small amount of fats and soaps, a large amount of sodium carbonate, to which the alkaline reaction is due, and pancre-

atine, which is probably capable of resolution into three ferments. Pancreatic juice is also stated to contain peptones, leucin and tyrosin, but it seems probable that these elements are not found in perfectly fresh juice, with the exception, may be, of a trace of leucin, but are formed through the digestion of the albumen in the pancreatic juice by one of its own ferments. I can show you the presence of some of these elements; the limited quantity of juice, however, will necessitate my employing very small quantities. On surrounding a small quantity with a freezing mixture, and cooling it down to 0° C., the fresh juice becomes gelatinous, again becoming fluid when warmed, and when exposed to a higher temperature it becomes entirely solid, like the coagulated white of an egg. A similar effect is produced upon the addition of the mineral acids, alcohol and an excess of magnesium sulphate, an effect not capable of production with ordinary albumen. The coagulum produced by alcohol is capable of resolution in water, and the coagulum of heat and acids is soluble in alkalies. When the coagulum of the albumen produced by heating fresh juice up to 72° C. is allowed to separate, the alkali-albuminate may be precipitated by acetic acid. The juice from the permanent fistula is more fluid, less coagulable by heat, contains a less amount of solids, and does not gelatinize in cooling.

While studying gastric digestion we saw that all its phenomena could be most conveniently studied with an artificial fluid; the same conditions prevail in the study of the subject now under our consideration.

Artificial pancreatic juice can be made by three different processes, and I here show you examples of each.

This specimen was obtained by mincing the fresh pancreas of a dog killed in full digestion, washing it to remove the blood, and then infusing it for two hours in four times its weight of water warmed to 25° C., taking care to keep the mixture at that temperature during the whole time of infusion. It was then filtered first through muslin and then paper, and since the filtrate was acid, from the development of fatty acids through the action of the ferments on the fats of the pancreas, it was neutralized with sodium carbonate. The filtrate is, as you see, slightly opalescent, from the presence of a small amount of fat in the form of an emulsion. This preparation has all the properties of pancreatic juice; the degree of its digestive action for proteids, however, will be dependent upon the nutritive state of the pancreas from which it was made. It contains all the elements of pancreatic juice. I will boil a portion, and there is quite a dense precipitate of albumen, and in filtering off this coagulum and neutralizing the filtrate with acetic acid, there is a deposit of alkali-albuminate. It also contains leucine and tyrosine.

This second specimen of artificial juice was made by first laying a minced pancreas, for two days, in absolute alcohol, which was then expressed off, and a glycerine pancreatic extract made in the usual manner and filtered. This preparation contains a considerable amount of the amylolytic ferment, but the quantity of the proteolytic ferment, as in the first, depends upon the condition of the gland.

The third preparation was made by mincing a fresh pancreas and rubbing it up in a mortar with powdered glass. For each gram of gland substance 1 cc. of 1 per cent. acetic acid was then added, and mixed thoroughly in the mortar for ten minutes, and then ten times its volume of glycerine was added, and the whole allowed to stand for three days. This preparation contains a much larger proportion of the proteolytic ferment than was obtained in either of the other processes, since the acetic acid has converted into ferment the zymogen or substance yielding the proteolytic ferment.

With these artificial fluids let us now examine the process and results of pancreatic digestion.

The most prominent and well-known fact in this connection is the power which the pancreatic juice possesses of forming a remarkably stable emulsion with fats. I will shake up two parts of the aqueous infusion with one part of olive oil, and a thick creamy emulsion is formed, which will stand for a long time: or upon adding two parts of the same infusion to one part of fresh lard melted over a water bath, and rubbing them gently together, we obtain an emulsion which will be permanent, even in the cold.

This emulsifying property is due to the alkali-albuminate of the pancreatic juice, for upon adding liquor potassæ to the first mixture, so as to dissolve the albumen, the particles of oil are set free and again run together. For the same reason the glycerine extracts will not form an emulsion with oil, on account of the absence of alkali-albuminate.

In addition to its emulsifying power over fats, pancreatic juice rapidly converts starch into glucose. I have here two test tubes, one containing starch mucilage, the other raw starch paste. To each I will add equal quantities of the aqueous pancreatic infusion, and after placing them for a minute or two in the water bath at 40° C.,

Fehling's test shows in both the presence of a large amount of sugar. We see here at once a difference between the saccharifying power of saliva and pancreatic juice; the former did not act, or, at least, for a very long time, on raw starch. This difference of action is only one of degree, however, and not of kind; both change starch into sugar through the presence of a ferment, and in both instances this ferment is destroyed by boiling; in fact, all that I told you in reference to this property, as instanced in the case of the saliva, might be repeated here, with the one modification as to the very much stronger amylolytic power possessed by the pancreas. In the case of the pancreas, at least, this saccharifying property is due to the presence of a ferment which is formed in the gland tissue by the transformation of some previously existing material, since it has been found that if the ferment is completely extracted from a fresh gland by glycerine, and the inactive residue be allowed to remain on the filter for five or six hours, exposed to the air, a further production of ferment occurs, and this new formation may be again extracted by water or glycerine. That this result is really due to a new formation of ferment, and not to the occurrence of decomposition, is proved by the fact that if the watery extract of a pancreas is once deprived of its action on starch by boiling, this power never returns in any stage of the subsequent decomposition.

We saw in our study of gastric digestion that the reaction of pepsine with fibrine and a dilute acid might serve as a means of recognizing the locality of gastric digestion in the lower animals, and Bernard has shown that the pancreas may always be recognized by its power of decomposing fats and forming fatty acids and glycerine. The entire process as proposed by Bernard is too lengthy to permit of my showing you all the necessary manipulations. I can, however, show you the fundamental facts, but for details will have to refer you to Bernard's original memoir. In the first place, you remember I showed you that the aqueous pancreatic infusion contains more or less fat, and if kept for a few hours at 40° C., without any addition, a strong acid reaction is developed from decomposition of the fat. I have here a specimen of pancreatic infusion, which about two hours ago I neutralized with sodium carbonate, and then added to it a little neutral olive oil, and then placed the tube in the bath at 40° C. I will now draw up with a pipette a little of this mixture from the bottom of the tube, and on placing it on a piece of blue litmus, a decided red is developed.

We have now to consider the digestion of proteids by the pancreatic juice, the most complex as well as the most important of its properties. This action is similar to that of gastric juice in so far as they both are due to the presence of a ferment which is destroyed by heat, and that they both convert proteids into peptones; there are, however, many points of contrast.

In the first place, we saw that gastric digestion required the presence of a dilute acid; in pancreatic digestion we will find that a 1 per cent. solution of sodium carbonate is as essential as was the .2 per cent. HCl. in gastric digestion.

I have here a test tube in which I have been digesting for two hours, at 40° C., several fragments of thoroughly boiled fibrine in an artificial pancreatic juice, made by adding a few drops of the glycerine-acetic acid extract to a 1 per cent. solution of sodium carbonate, and you see again a marked contrast between this result and what occurred under similar circumstances with gastric juice. At first sight it would appear that the fibrine was entirely unaltered, but on stirring it with a glass rod it is easily torn, and many of the smaller fragments dissolve, and on removing some of the larger pieces, and washing them with water, they are seen to be corroded and as opaque as before, and not swollen and transparent, as would occur in an analogous stage of gastric digestion. Besides these superficial changes, however, the attributes of the fibrine have been very considerably modified. You remember that this fibrine was boiled, and that boiled fibrine is not soluble in dilute acid. I will place a few fragments of this boiled fibrine in a .2 per cent. solution of hydrochloric acid, and it very rapidly dissolves, forming a solution of syntonin, which I can precipitate upon neutralization. Here is, then, one of the distinctive features of pancreatic digestion. Before being dissolved, boiled fibrine is rendered more soluble in dilute acids than even raw fibrine, which you know will not dissolve for many hours.

There is another remarkable fact about this stage of the pancreatic digestion of boiled fibrine: the fibrine becomes soluble in a 10 per cent. solution of sodium chloride. I will rub up another fragment with a 10 per cent. salt solution in a mortar, and when it dissolves filter. Now, to one portion of this filtrate I will add nitric acid, and another I will boil; in both there is a precipitate.

Having thus seen that the first step in the pancreatic digestion of boiled fibrine is to change it to a soluble albuminous substance somewhat resembling raw fibrine, let us now examine the subsequent stage in the process. I will boil a

portion of this artificial juice in which the fibrine has been dissolved, and there is a precipitate formed. I will neutralize another portion with acetic acid, and I again obtain a deposit. This is again a difference from gastric digestion, for although the alkali-albuminate precipitated upon neutralization is analogous to the parapeptone, the albumen coagulable by heat is entirely unrepresented in any known product of gastric digestion.

To examine the further stage of this digestion I will make use of another specimen of pancreatic juice entirely similar to the first, with the one exception, that the fibrine was subjected for five hours to the action of the juice instead of two. I first neutralized it with acetic acid, and then boiled and filtered it, to remove whatever albumen still remained undigested. It was then evaporated at 65° C., to about one-third its bulk, and an excess of absolute alcohol was added while still hot, and after standing for twenty-four hours the precipitate which had formed was collected on a filter. Now, on dissolving this precipitate in water and applying the usual tests, we recognize the presence of peptones entirely similar to those produced in gastric digestion, with the doubtful exception as to their being precipitable by acid. The amount of peptones, however, obtained in this instance, falls far short of the amount of fibrine which had been digested, and the longer the pancreatic digestion is continued, the greater this apparent loss. This loss, however, appears to be counterbalanced by the appearance of two crystalline principles, leucin and tyrosin, which apparently result from the breaking up of the proteid substance which may be undergoing digestion.

After filtering off the peptones, I evaporated the alcoholic filtrate to a small bulk, and allowing it to cool, I obtained these crystals of tyrosin, in white acicular tufts, and on pouring off the mother liquor leucin crystallizes out in white shining scales. The mother liquor also contains naphthilamine and indol, bodies formed in the last stages of pancreatic digestion.

The presence of naphthilamine is shown by adding gradually to the mother liquor, diluted with water, a little chlorine water, when a rose-red color is developed. Indol, to which apparently the peculiar odor of fæces is due, is recognized by its forming a red color with dilute nitrous acid. As a very dilute acid is required for this reaction, it is most conveniently obtained by boiling a little glucose in a test tube with nitric acid, and when the tube is filled with red fumes, pouring out the acid and filling the tube with water. On now boiling this solution with a little dilute mother liquor, the characteristic red is developed. There is some doubt, however, as to whether indol is properly a result of pancreatic digestion, or is due to decomposition, as it has been claimed that when pancreatic digestion is carried on in the presence of salicylic acid no indol is formed.

Attempting now to explain the phenomena of pancreatic digestion, we must adopt, with Kühne, the view that native albumen or fibrine can be split up into two elements, which he terms respectively an anti-residue and a hemi-residue. When subjected to either peptic or tryptic (the proteolytic ferment of the pancreas) digestion, albumen, or other proteid, is split up into an anti-peptone and a hemi-peptone, the former being incapable of further digestion by either ferment, while the latter is capable of the further resolution under the action of trypsin into leucin, tyrosin, etc. In both instances, before the stage of peptone is reached, there is an introductory stage corresponding to the formation of syntonin, which, however, is termed respectively hemi and anti-albumose. The anti-albumose is apparently identical with syntonin, and is convertible only into anti-peptone, while hemi-albumose seems more closely to coincide with Meissner's a-peptone, and resembles myosin in that it is soluble in a 10 per cent. sodium chloride solution. Hemi-albumose is convertible into hemi-peptone, and under the action of trypsin, into leucin, tyrosin, etc.

Applying these views to the decomposition of proteids by acids, dilute hydrochloric acid at 40° C., gives rise, on the side of the hemi group, to hemi-albumose, and so to hemi-peptone, and by the action of sulphuric acid at 100° C., the hemi-peptone is further reduced to leucin and tyrosin. On the side of the anti group these agents, as well as an imperfectly acting ferment, give rise to what Kühne terms anti-albumate, which is evidently the parapeptone of Meissner, and is incapable of any further change under the action of pepsin, but under trypsin becomes anti-peptone (Foster).

—Official reports, made under a law which came into force in May, indicate that the adulteration of articles of food and drink is carried on to an alarming extent in Germany. In Berlin, 700 specimens of sausages were examined, and all were found to be bad. Chocolate, wine, milk, beer, brandy and soda water, in more than half the cases examined, were found impure and adulterated.

Communications.

CLINICAL STUDIES OF INEBRIETY—SOME OBSCURE SYMPTOMS.

BY T. D. CROTHERS, M.D.,
Superintendent of Walnut Hill Asylum, Hartford, Ct.

The early symptomatology of inebriety has never been studied. Patients are rarely ever seen by physicians until they become chronic, and then only for temporary relief of some acute stage or condition.

They seldom go to an inebriate asylum until every other means has been tried and failed, and the clinical study of such cases is always difficult, requiring time and patience. Of the early history of such cases the patient's memory is often very clear, and more reliable than at later periods, and to those accustomed to study these cases, having once determined some prominent early symptom, the others can be readily traced. Although we are not able in our present knowledge to follow out all the stages of these cases from day to day, yet the marked similarity of the principal symptoms is conclusive evidence that we are dealing with a disease which follows a regular course, governed by causes and conditions which will be understood with a larger knowledge of the subject.

All our clinical studies fail to support the theories of vice and disease, and distinctions of responsibilities, etc., which are so confidently put forth by many who assume to know, without special study of individual cases.

In some previous articles on this subject in the Reporter we have stated that inebriety was always preceded by certain conditions and symptoms which might be recognized by practical observers.

We now propose to group some of the most significant of these early symptoms, and indicate their pathological bearing, with a view to direct the attention of physicians to further studies in this direction.

These cases are selected because of the comparative accuracy of the early history, as noted by friends and the patients themselves.

Case 1.—Inebriety Preceded by Delusions of Food and Drink, and General Eccentricity.

O. B. had a drunken grandfather on his mother's side. Both parents were strong, healthy people. His mother was a very pious, conscientious woman, and died of some affection of the heart, at 45 years of age. His father died at 56, of pneumonia. All his brothers and sisters were healthy. After graduating from college, when 21 years of age, he became deeply religious, and commenced to keep a minute diary of his thoughts and feelings. From this record we are able to draw many of the following facts:—

At this time he was healthy and perfectly temperate in all his habits, and a man of good average ability, with much general culture.

After completing his theological course, he was installed over a large village congregation. About this time appeared what I shall term dietetic delusions. He considered that solid foods were injurious, and began to live almost altogether on soups and milk. A year later he changed this for a diet of solids, using all kinds of food, except meats, and drinking freely of water at all times.

He then conceived the idea that the care of the body was the highest religious duty of man, and both acted and preached this doctrine. He would change his dress several times a day, to suit the changing temperature, and gave the greatest attention to all that he ate and drank.

St. Paul's ideal of "keeping his body under and bringing it into subjection" seemed to be the ambition of his life. He expressed great fear that the animal part of his body would gain the ascendancy, and thus avoided all conversations and readings of crime and disaster. All his leisure was spent in exercising, bathing and contemplations of spiritual themes. During this time he preached against intemperance and the abuse of the body, with much vigor and earnestness. Then he became interested in the physiology of food, and planned out an elaborate system of diet and weighing of foods, which was used every day. His diary during this time is a curious medley of reflections on this subject and plans to build up the body and develop the spiritual condition.

In the meantime he married and became a professor in a college; all his delusions continued, although changing in both the object and system to be pursued. He was evidently at this time neuræsthenic, and complained of nervousness and exhaustion; also was easily agitated and extremely sensitive to the changes of weather. Had a great dread of society and excitement, and was treated by a physician for anæmia and muscular rheumatism.

He imagined that he was suffering from Bright's disease of the kidneys, and increased his care of both food and drink. In appearance he was the picture of health, and mentally was quite active, writing and teaching with all his usual vigor.

His wife died suddenly, and the loss seemed to

rouse him to greater exertions and efforts to care for himself. He published a book on food and drink, full of extreme views, for the purpose of proving that the origin of all disease and vice came from the quality and quantity of food.

After a six months' tour in Europe he returned a wine drinker, with all his old notions exploded. At first he drank secretly, then openly, giving no reason for this change. He complained of dyspepsia and heart disease, and resigned his professorship. A few months later he accepted a situation as a clerk, and from this time went steadily down to a confirmed inebriate; using brandy nearly every day, to intoxication. Muscular tremblings and anaemia, with general congestion, were present. The only delusion present was fear of sudden death from spontaneous combustion. His religious habits were kept up, but the care of his body and the food were neglected.

He continued to write, in a sad, dreary way, of the conflicts of the animal part of his nature, but made no efforts to recover. He was reckless and untruthful, boasting of things which did not exist, and using violent language when opposed. He expressed a desire to recover but made no exertions to accomplish it. His memory was obscure, and at times he seemed to have periods of extravagant hopes and expectations. Six months' residence in an asylum was followed by a general improvement of both body and mind, and he was discharged, and is to-day temperate and occupying a responsible position. Within a few months the reappearance of all the old dietetic delusions has given his friends just cause for alarm, and without doubt they will lead back to inebriety sooner or later.

The prominent symptom here was morbid fears or dietetic delusions about food and drink. Although a cultured, sensible man, he never realized their morbid, diseased character. While in Europe the use of wine acted as a spark exploding these impulses and developing the very animalism he sought to check. It is possible he may have realized unconsciously the danger which he inherited, and sought to avert it by such means; or this strange development of symptoms, along with a religious change, may have been a symptom of inebriety in the future.

Case 2.—Inebriety Preceded by Religious and Dietetic Delusions.

M. was a farmer, whose parents were both consumptive. His father and two of his uncles drank hard, and one of his brothers was eccentric and became insane. His parents died when he was 13 years old, and he went to live in the family of a very pious uncle. Here his religious character was developed to a high degree. An ambition to be a missionary like St. Paul filled his mind, only he trusted to faith alone and the call of the Spirit, without the addition of works, thinking that all the means would be at his command when the time came. For several years he worked on the farm with his uncle, confidently expecting some revelation and direct call, with a miraculous gathering of the means.

His sisters, who married and lived near, had fears of his mental condition, and hence watched him carefully. At twenty-two he became an energetic temperance man, lectured and held meetings about the town he lived in. He conceived the idea that all drunkenness came from the use of animal food, and began to study the effects of foods on his body. He changed his religious views, and considered that the care of the body was the sole object of life, and talked incessantly about the laws of nature and their abuse. He used only vegetable food, and that very sparingly. Believing that he had spermatorrhœa, he went to a "Quack Water Cure," and after two months came back more eccentric in all his habits and conceits of food and drink. From this time he worked as usual on the farm for five years, when his uncle died and he came into possession of the farm. He married, and a few years later he began to drink cider freely, urging as a reason that his system needed an acid. Some months after he came home from a temperance meeting intoxicated, and although he was more enthusiastic than ever in all his delusions of food and drink, he drank at times, and was intoxicated, without any excuse, except, according to his views, the indigestion from some kind of food which he had not understood. As an instance of these delusions, he attributed to the meat dressing on food, and the mode of preparation, and to the animalcula in water, the cause of his desire for drink. His mind seemed to grow more feeble, and his whims manifest themselves in business and all intercourse with his neighbors. He was seized with typhoid fever, and after recovery drank hard from day to day. Signing the pledge and promising his friends that he would not drink again, and yet going deliberately away without any thought of what he was doing. He seemed to lose all consciousness of right and wrong, and forgot that he had promised or wanted to abstain. His body and mind became so much impaired that he was at last sent to an insane asylum, where, after three months' residence, he recovered in part and returned. The old delusions of being a missionary, and of miraculous means open to

enable him to accomplish this end, has come on again. He is a very temperate, conscientious man, and is an eccentric reformer in the temperance ranks. In the asylum he was stolid and forgetful, full of delusions himself, although he reasoned well about matters outside, and was on all other subjects free from any noticeable peculiarities. He was alarmed lest his wife would desert him, and thought his stay in the asylum had a sinister motive; supposed his property would be taken from him. He eat heartily at times of all kinds of food, then abstained, and all the aches and pains he attributed to the presence of bad food.

This case was particularly noticeable for the delusions of faith and of food. In all probability the spermatorrhœa was largely nervous, and the treatment and residence with the *Water Cure* only served to rouse and intensify the nervous trouble. His enthusiasm in the temperance cause was of the same character, only varied as to object, and destined to break out into inebriety sooner or later, under any circumstances.

Case 3.—Inebriety Preceded by Delusions of the Care of the Body, Fear of Death, and Temperance Enthusiasm, etc.

B. Both parents died of consumption when he was six years old. He was brought up on a farm, and was a strong, temperate, retiring young man, free from all peculiarities or noticeable weakness. When twenty-four he was employed as express messenger on the railroad. Three years later he married, and his wife noted the following curious habits, but in reality symptoms. He drank milk in preference to tea and coffee, which he supposed to be adulterated, and had great fear of being poisoned by water. He lived on a diet of rice, potatoes and apples, and was constantly studying the food which he thought would prevent disease. He talked confidently of the theory that each person required certain kinds of food to prolong life and avoid disease, and the study of these foods was the great purpose of life. He read largely of the popular scientific literature of the day, and adopted many curious notions and opinions. He was in good health, and in no other respect was he peculiar or strange. These fancies and whims grew more prominent each year. At one time he lived on a vegetable diet, and wrote out minutely every day a description of his feelings and condition; then he changed to a meat diet almost exclusively.

He gave great attention to the care of his body, regulating all his habits with mathematical precision, reading much, and exhibiting a passion for histories of the Rebellion, and spending hours in calculations of the greater endurance of the armies if the proper diet had been used. He attended closely to his business, was *particular* and *fussy*. Could not bear to do anything out of time, and was very sensitive about little interruptions. All these peculiarities grew steadily upon him, making themselves prominent to those in his company. His health was good and his temperance enthusiasm increased, until he became a lecturer, seeking every opportunity to speak to and exhort audiences of young men. He joined all the temperance societies, and was very active. About this time he manifested great fear of death and loss of property, and seemed to have delusions of caution; he bought tickets in Travelers' insurance companies every day; giving particular caution to the inmates of his house about fire, changing his will frequently, and making a special statement in his diary of what he wished to have done. Later, he gave up the express business and went to farming, manifesting the same caution and changeableness of purpose and plans; he had an attack of remittent fever, which increased his delusions of disease and turned his attention to remedies and means for recovery. Anæmia, neuralgia, with a general condition of neuræsthenia came on. He began to use all kinds of quack medicines, and at last found relief in some bitters which contained large quantities of alcohol, which he drank regularly from day to day. From this time he went rapidly down, drinking to intoxication, neglecting his business and losing his property, and becoming an aimless, chronic drunkard. His friends finally sent him to an asylum; he was full of delusions of persecution, was passionate and very childish in thoughts and impulses. After six months' residence and treatment he recovered and was discharged, and moved to the far west. His mind regained to a large extent its control, and the old delusions had passed away.

These three cases bring out prominently the peculiar class of symptoms which I am confident both precede and follow many cases of inebriety. Neuræsthenia, with both functional and organic nerve disturbances, is present in nearly all the cases. They all follow in the line of many of the complex physical symptoms which are so puzzling to the ordinary observer, and indicate, without doubt, the disorder of some brain centres or some general condition of debility.

The presence of these early symptoms is not always followed by inebriety, but they indicate a condition that lies closely along the "border

land" of this disorder. A condition which, with a slight change of circumstances, develops inebriety at once; all the soil is ready, only needing the germ to spring into activity.

These cases can be studied in nearly every community, and are seen often in the enthusiastic temperance men, who have a half consciousness of their danger, and hence are more active to help others, and by this means save themselves. These symptoms are of grave importance when developed among brain workers, because, all things considered, less power of resistance and capacity for recovery exists.

Delusions and morbid convictions and introspections of the mind impress the brain more permanently in some cases than in others, and their presence in any case is a hint of much pathological importance.

These clinical facts may be condensed into the following statements:—

1. Extreme solicitude for the care and protection of the body, as well as the food and fluids used, when it becomes a delusion, absorbing the thoughts and energies, is, as a rule, an early symptom of inebriety.

2. Delusions of fear, faith, and extreme anxiety for the temperance reform, in persons not intemperate before, accompanied with changing emotions and unstable nerve conditions, are significant symptoms, very often ending in inebriety.

Hospital Reports.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

SERVICE OF PROF. LOUIS A. DUHRING, M.D.

Reported for the Medical and Surgical Reporter.

Erythema Nodosum.

The patient was a little girl, five years of age, whose legs, thighs and arms were the seat of a number of flat nodules, from half an inch to an inch in diameter, slightly elevated above the level of the surrounding skin, having a smooth surface without scales, and a dark reddish or purplish color. There was no sensation of itching, nor of burning, but the child said that the lesions were painful. There was no eruption of any sort on other parts of the body. The affection had made its appearance about a week previously, showing itself originally upon the legs, the lesions being at first of a more vividly red color, but within a day or two becoming quite dark or livid. They came out one or two at a time, new ones appearing every day, and within a few days the thighs and also the arms became involved. At the time of her appearance in the clinic the disease appeared to be at its height. The patient's general health had not been very good, especially of late; her appetite was capricious; her bowels were constipated; she was subject to headache.

Dr. Duhring said that the history of the affection was quite characteristic. Erythema nodosum was an uncommon affection in this clinic. When cases came under observation, it was usually in the later stages of the disease. The lesions look very much like bruises; a slight circumscribed tumefaction of the skin occurs, which is first of a bright red color, but this soon grows darker, purplish, livid, and finally runs through the various shades of blue and yellow which mark the changes taking place in a bruise. This resemblance to a bruise has given rise to the name *dermatitis contusiformis*, formerly applied to the affection, a name which is now quite obsolete. It shows, however, how the appearances presented by this affection impressed those who first saw it. Many colored plates representing erythema nodosum represent the lesions as much more prominent than in the present instance; the wax models in the University Museum show protuberances nearly the size of a half walnut. The present size, the lecturer said, was more usual. This affection, Dr. Duhring continued, was in reality a phase of *erythema multiforme*, of which another variety, erythema papulatum, was that at times observed on the backs of the hands. The treatment of erythema nodosum should be as simple as possible; often no treatment is demanded. Saline drinks may at times prove beneficial. In order to allay the mother's fears, general directions and advice should be given. Rest should be enjoined. Locally, if there is pain, cold compresses or a roller bandage may be employed. The affection ordinarily runs its course in a fortnight, and gets well spontaneously. The diagnosis is important. In the present instance it was easy, but in cases where only a single lesion shows itself at a time it is sometimes difficult to distinguish its exact character, and it might easily be confounded with threatening abscess or with erysipelas.

Urticaria.

A laboring man, about 30 years of age, presented himself without any distinct lesions, but showing numerous scratch marks upon different parts of the body. He had been troubled, he said, for several weeks, with "hives."

Almost every one, Dr. Duhring said, knows the lesions of urticaria, for they are striking, and the disease also is common and well known among all classes. But the lesions are fugitive, and it is often difficult to get an opportunity to inspect them. The patient states he has had "hives," but at present none of the characteristic wheals of urticaria are to be seen; we see, however, scratch marks scattered over various parts of the surface. Now scratch marks and excinations are not in themselves characteristic; they may be present as the only conspicuous lesions in phtheiriasis as well as in urticaria. We must take this into consideration, for phtheiriasis may occur in all walks of life, and in a case of eruption like the one before us we must not hesitate to examine our patient for pediculi, no matter how high his social position. Here we find the clothing quite free from lice or nits. If we come back to the scratch marks again and examine these, we see that they are not so numerous as they would

be if the disease were phtheiriasis. Lice multiply very rapidly, and if they had been present here for six weeks, which our patient tells us has been the duration of his disorder, the ravages which they would have committed by this time would have been much more marked in their effects. Let us now attempt to develop some wheals artificially. (Dr. Duhring here drew the edge of his finger several times across the surface of the skin, over the back, so as to produce a gridiron arrangement of lines.) This man's skin, you note, is in a very sensitive condition; you observe that already there are white raised wheals beginning to form, arranged in cross lines just where my finger has been drawn. This indicates positively the nature of the disease. We have here urticaria, and the condition, whatever it may be, which has given rise to this susceptibility of the skin is still in operation.

Urticaria may be either acute or chronic, that is, it may consist of an attack lasting some hours or days, or it may recur indefinitely and last weeks, months or years. The acute variety is most frequently brought about by the ingestion of certain kinds of food, strawberries, shell fish, etc. The chronic variety is usually dependent upon some, it may be obscure, functional disorder of the nervous, or digestive, or, in women, of the generative system. While the external treatment in urticaria is the same, whatever the variety or the cause, the internal treatment differs. On questioning our patient, we find he shows positive signs of indigestion. We shall therefore direct that he take a sufficient quantity of Rochelle salts, morning and evening, to produce several copious evacuations in the twenty-four hours. He shall also be ordered four grains of quinine, to be taken three times a day. In addition, the patient's diet must be regulated. He must avoid pastry in every form; pickles, salt meat, cheese and crude vegetables, must also to be eschewed. In ordering local treatment for a case like the present we should prefer lotions, as they are more apt to give quick relief to the intense burning and itching. The following is a useful formula:—

R.	Acid carbolic,	f. ʒ j ad iij	
	Glycerinæ	f. ʒ ij	
	Aquæ	ad . Oj.	M.

Another one which is equally good and useful, is this:—

R.	Alcoholis	f. ʒ ij ad vj	
	Glycerinæ	f. ʒ ij	
	Aquæ	Oj.	M.

Sometimes one of these lotions is the better, sometimes the other. They are both very convenient and useful. Alcohol, brandy, whisky or other liquor, pure, may also be used.

Cornu Cutaneum.

Jane McC., seventy years of age, presented herself for the relief of a horny growth situated on the left cheek, over the malar eminence. This was about an eighth of an inch in diameter, and about half an inch in length, rising abruptly from the skin and standing out at a right angle from the surface. It had first been observed about ten months previously, as a minute, hard scale upon the surface, which itched slightly, and when picked off rapidly grew again, and had increased steadily, although very slowly, in size, up to the time of the patient's presentation before the class. On the vertex of the scalp could also be observed a sebaceous cyst or wen, the size of half a walnut, quite without sensation, and of many years' duration.

Dr. Duhring called attention to the characteristic features presented by this cutaneous horn, which, though small, was quite typical in its appearance. It starts, he said, directly from the skin, without any raised base or areola. It may be freely handled without pain, and on examination we find the growth in no way different from that of an ordinary horn growing upon one of the lower animals, being hard, laminated, and grayish in color. We may meet such horns growing upon any portion of the body, especially where the sebaceous glands are active; the face, neck, shoulder, hands, and even the glans penis in the male, may be the seat of the growth. (Dr. Duhring here showed several pictures of cutaneous horns, one of which, about three inches in length, grew from the back of the hand of an elderly person. Although firm to the touch, such small horns as this can be picked off without difficulty, leaving an excoriated or ulcerated base. The pathology of cornu cutaneum is simple: it springs from the deeper strata of the mucous layer of the epidermis, and consists in a hyperplastic growth of these cells.

Many cases of cutaneous horn have, from year to year, been reported in the journals, especially in former years. Of late they seem to be less frequently met with. As people become more enlightened they are disinclined to allow such growths to remain, and they are removed before they grow large. In this case the patient shall be directed to poultice the horn for a day or two, in order to soften and macerate it thoroughly, when it will probably come off spontaneously. But if the base be not destroyed, it will grow again, and we shall therefore direct that it—the base—be cauterized with one of the stronger caustics, say with caustic potassa. This will effectually prevent its recurrence.

In connection with this case, Dr. Duhring recalled a similar one, which had applied at the clinic about a year previously. This occurred in an Irish laborer, some fifty-six years of age. He had first noticed it about four months before, when the lesion showed itself in the form of a pin-head-sized papule, on the left side of the face, just in front of the ear. This grew slowly at first, afterward more rapidly. At the end of two months it began to harden, the surface grew horny, and when the patient came under observation he showed a well marked horn, flattened like an elongated, thickened and pointed claw or toe nail, more than half an inch in length and one-third of an inch in breadth at its attachment. It was quite movable upon its base, which was a raised fleshy tumor, the size of a small filbert, and presenting the appearance of a sebaceous tumor. The patient was seen again two months later, when the horn was found to have nearly doubled in length, preserving the same general shape, and lying flat against the skin, though only attached by its rather narrow crescentic base. At this time the horn was quite loose, and could easily have been picked off with the fingers.

Verrucous Growth of the Scalp.

A boy, about twelve years of age, was brought before the class showing a flattened, elongated warty growth on the right parietal region, about two inches in length by half an inch in breadth, and rising a quarter of an inch or more above the surrounding skin. The color of the growth was pinkish, while the neighboring integument was quite red, smooth, infiltrated, and showed a number of small pin-head-sized, pearly nodules or milia, filled with cheesy matter. There were no hairs proceeding from the growth itself, and the scalp in the immediate vicinity was quite bald. The growth was made up of a large number of small warty excresences, closely pressed together, and exuding, when pressed upon, a yellowish fluid from their interstices. There were no subjective symptoms. The growth had shown itself some years previously, as it was stated, a common wart upon the scalp, which grew with considerable rapidity and spread until it had reached the size presented. Prof. Duhring called attention to the absence of hair upon or in the immediate vicinity of the growth. This had been caused, in part, he thought, by mechanical means, and in part by inflammation and subsequent closure of the hair follicles. Had this growth occurred in an elderly person, it might give rise to some concern as being the probable starting point or seat of epithelioma. Even in a boy, if allowed to run on, such a verucca might, in time, give trouble, for epithelial degeneration might occur, with subsequently the formation of epithelioma. For this reason the growth should be removed, and the application to be recommended in this, as in the case of warts generally, is glacial acetic acid. This is to be applied by means of a small stick covered with cloth, or a mop, with which the acid may be rubbed in once or twice a day, until the warty growth becomes tender. Some time will probably be necessary to bring about its disappearance.

The Treatment of Dyspepsia.

On this subject Dr. A. Leared says, in the *British Medical Journal*—

"In the treatment of all forms of dyspepsia attention to diet claims a prominent place. Articles known to be slow of digestion must be avoided, and a lessened amount of food must be taken only at proper times. But, as a rule, absolute strictness in diet is more necessary in dyspepsia from defective secretion than in that from impaired motion; for, as already said, in the latter affection digestion is sluggish rather than imperfect. One dietetic rule is, however, of the greatest importance in the present case. The principal meal should be taken early in the day, before the nervous system has been exhausted either by mental or by bodily exertion. In some instances the power of digestion seems to diminish in proportion as the day advances. A distinguished literary lady consulted me, who had, by incessant brain work, fallen into a state of great suffering from gastric oppression and flatulence after meals. At my suggestion she dined early instead of late in the day. This change was beneficial, but was not effectual in affording relief. I then advised that she should eat meat at breakfast only, and that no writing should be done before the meal. This plan succeeded perfectly.

From its well-known power in causing muscular contraction, strychnia suggests itself as the remedy for impaired gastric peristalsis. It affords the most powerful means we possess of restoring the gastric functions. I may, perhaps, take some credit for having helped to make known its value. So long ago as 1860, I wrote: "Speaking from extensive experience, I know no single medicine of more value. . . . . It acts by increasing the tone of the muscular coats of the stomach and intestines. When these coats are relaxed, gases are generated, mainly owing to retardation of the aliment in the cavities. No remedy has in my hands proved so permanently effective as strychnia against this inconvenience." (*Imperfect Digestion* 1st ed., p. 186.) In 1864 the late Dr. Brinton, following Chomel, condemned the use of strychnia in stomach diseases as unnecessary and dangerous. (*Diseases of the Stomach*, p. 334.) But, notwithstanding the condemnation of these authorities, strychnia has held its place in these affections, because, although too often given without discrimination, it proves beneficial in many instances. The secret of its successful administration lies in the recognition of the cases. It is suited for cases characterized by the symptoms of impaired motion; namely, uneasiness, but not actual pain, after food, and flatulence. It is not suited for cases of impaired secretion, characterized by pain after food and little or no flatulency.

Some precautions are, of course, necessary, and more so because the patients are seldom under daily observation. A dose of one-twentieth of a grain should rarely be exceeded. It should never be given in pills, on account of the difficulty of exact subdivision in that form. The susceptibility of the alkaloid to precipitation by alkalies and some other substances must be kept in view. If so precipitated, the whole of the drug would, of course, be contained in the last dose in the bottle. For the rest, the pharmaceutist must be responsible. But, after having prescribed strychnia some thousand times, I never knew any harm to arise from its use.

It might be supposed that electricity would prove useful for lesions of peristalis; but after many trials of faradization and a few of the direct

current, I am compelled to say that I do not regard it as a useful agent in this affection.

It is sometimes desirable to check flatulence by some agent which hinders fermentation. Formerly, I prescribed carbolic acid for this purpose; but its unpleasant taste is a great drawback. Of late, I have used thymol with, I think, better results; and the taste is far less objectionable.

Many cases are met with in which the stomach is unable to expel flatus in consequence of temporary paralysis from over-distension. Various drugs given to promote contraction of the organ —carminatives, as they are called—sometimes fail in their purpose. It is in such cases that charcoal proves useful. Charcoal possesses a remarkable power of absorbing gases; but this power, as I have elsewhere shown, is very much lessened by long keeping and by wetting. This led me to the plan of giving, in hermetically sealed gelatin capsules, charcoal prepared from vegetable ivory, which kind was proved by experiment to possess the best absorbing power. If, in cases of obstinate gastric distension, three or four such charcoal capsules be swallowed, a few cubic inches of carbonic acid gas will be speedily absorbed. Tension being now removed, the muscular coat of the stomach generally resumes its power, and flatus is freely expelled. In a few obstinate cases, however, chiefly when the stomach affection is secondary to diseases of the liver or kidneys, the muscular paralysis is so complete that, as happens in case of the over-distended *rumen* in cud-chewing animals, mechanical interference is the most effective mode of treatment. For this purpose, I have had made a small India-rubber tube (tube shown) two feet in length, having one extremity closed, and perforated like a drainage tube to the distance of four inches from the end. Such a tube can be safely and easily introduced into the stomach, and will prove effectual in relieving the distended organ.

The Neglect and the Value of Blistering.

Dr. H. S. Anderson, in his Harveian Discourse, published in the Edinburg *Medical Journal*, says—

A remedy which I fear is somewhat unduly neglected now-a-days is counter-irritation by means of blistering; and I think I have observed in some young practitioners an approach to something like terror when blistering is spoken of as a remedy that may frequently be used. Certainly, as regards children's diseases, there is more of this fear than there should be. It has frequently, for example, been my experience to see children, in consultation with a younger practitioner, when blistering in acute head affection had never been dreamed of. In mostly all acute inflammatory affections of the brain, tubercular or not, in children, I am strongly of opinion that after shaving the head the application of blistering fluid has a most rapid and satisfactory effect. Inflammatory attacks also, of the peritoneum and chest, in children, are often controlled by blistering, although the size of the vesicatory and the length of time applied must be carefully considered. And in the rheumatic affections of the joints, in adults, repeated blistering has often the happiest results. For many chronic conditions also, counter-irritation has always held a high place in my list of remedies. In chronic tubercular affections of both chest and abdomen, I think occasional and repeated blistering is frequently beneficial, and also in chronic and obscure head and other affections of the nervous system. For example, a blister over the roots of the nerves, in herpes zoster, often relieves the neuralgic pain so generally present, and often so difficult to get rid of. In diphtheritic paralysis, also, blistering the nape of the neck, and even down the spine, often expedites cure in a wonderful way. In the uterine or ovarian pain so often complained of in the left side, there is no better remedy sometimes than a succession of fly-blisters, and the tenderness of spinal irritation is very frequently relieved, if not got rid of, by the same means. In chronic effusions the use of blisters is still fully acknowledged, and does not therefore call for special mention.

Treatment of Cholera Infantum.

The following treatment is recommended by Dr. W. Frank Hines, of Maryland, in the *Southern Clinic*:—

Nothing is of more importance in this trouble than the diet. The practice of giving farinaceous substances—cracked wheat, tapioca, farina, etc.—is surely wrong and hurtful. The digestive organs of the child are very weak, and to put anything in them which they have not been in the habit of receiving is to over tax them; milk contains all the necessary ingredients for the support of the infant; but it does not contain any starch. If possible, the child should be fed on "mother's milk." If this is not practicable, cow's milk may be made to answer. Condensed milk I have seen act in a very satisfactory manner, when there is great prostration and weakness. Beef tea, with a little brandy in it, is very beneficial; say a teaspoonful of beef tea with half a teaspoonful of brandy, every three hours.

In regard to medication, I do not think a great deal is needed, except when there are frequent discharges. They must be stopped; if not, the child will die from weakness. In this connection the following treatment has been of great service:—

℞.	Bismuth. sub. nit.,	℥ ss	
	Spts. ammon. arom.,	℥ ij	
	Tinct. opii camph.,	℥ iss	
	Syrup simplic.,		
	Aquæ fon.,	āā ℥ ss.	M.

Sig.—Teaspoonful every 2½ hours to child 1½ to 2 years old, according to condition.

In some cases, where the diarrhœa is of a very persistent character, stronger measures will have to be resorted to; these are best determined by the circumstances of the particular case. The temperature should be kept down; there is nothing better for this purpose than quinia; but as there is generally head trouble in these cases, I do not think it advisable to use it. Cold cloths applied to the head, sponging with cold water, and ice water cloths to the abdomen, will lower and keep down temperature very satisfactorily, besides often relieving the head trouble.

The Question of Tying the Cord.

The *Annales de Gynécologie*, for February, 1879, contain a paper on this subject, by Dr. Alban Riebemont. He sums up his paper as follows:—

1. By ligating the cord late the infantile circulation receives on an average an addition of 92 grams of blood (Budin).

2. This blood, which is contained in the placental vessels, is most necessary for the full establishment of the infantile circulation.

3. The blood is drawn into the infantile circulation chiefly by the suction power exerted by the expansion of the chest walls (Budin), the pressure exerted by the uterus on the placenta (Schücking, Porak) having no considerable effect.

4. In cases of asphyxia, where the child has a bluish hue, the cord ought not immediately to be tied, nor should any hemorrhage be permitted from its fœtal extremity.

5. Ligating the cord late does not expose the child to the smallest immediate or ulterior danger.

6. The infant is thereby placed in the most advantageous circumstances possible for its development; it loses less weight, and regains what it has lost both sooner and quicker than if the ligature be made immediately.

7. The expulsion of the placenta is thereby rendered easier, and there is less resistance offered to its escaping through the cervix (Budin, Schücking).

8. He agrees with Hofmeier, Zweifel, Schüching and Budin, that the cord should not be tied till the pulsation in it has entirely ceased.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——The proceedings of the American Medical College Association, at Atlanta, in May, have been published in pamphlet form, and copies may be had of the Secretary, Dr. Leartus Connor, Detroit, Mich. (Paper, pp. 14.)

——In pursuance of his fruitful studies on nervous diseases, Dr. George M. Beard, of New York, has recently had reprinted two of his articles, one on "Other Symptoms of Nervous Exhaustion," the other on 125 cases of Writer's Cramp and Allied Affections. They are well worth careful perusal.

——The seventh "Toner Lecture" was delivered by Dr. Edward O. Shakspeare, of this city, on the subject, "The Nature of Reparatory Inflammation in Arteries after Ligature, Acupressure and Torsion." It is a thorough study of the literature of the subject, illustrated by a number of original observations, and must prove of interest to all pathologists and surgeons. (Washington Smithsonian Institution. Price 25 cents.)

——Of gynecological reprints, we acknowledge one on the "Pendulum Leverage of the Obstetric Forceps," by Dr. A. H. Smith; on the "Hand as a Curette in Post-partum Hemorrhage," by Dr. H. P. C. Wilson; and a paper on the "Causal Lesions of Puerperal Convulsions," by Dr. James Tyson." The last mentioned goes to show that some form of Bright's disease is usually the exciting cause of convulsions. It is a reprint from the *Transactions* of the Pathological Society of Philadelphia. (pp. 56, 8vo.)

——Dr. Edward S. Dunster, of the University of Michigan, delivered, at the last meeting of the American Medical Association, a very able argument against a proposed amendment of the code of ethics restricting the teaching of students of irregular or exclusive systems of medicine. Indeed, we heard it characterized by a person present as the very best effort made at the meeting. The full argument now appears as a pamphlet of twenty-eight pages, with some appropriate accessory matter. Dr. Dunster has the right side, and he marshals his arguments with great skill and force.

——The radical cure of hernia by tying together the walls of the ring with carbolized catgut ligatures was effected by Dr. H. O. Marcy, of Cambridge, Mass., as far back as 1871, and several cases are recorded in his paper before the last meeting of the American Medical Association. He writes—"No method of operation for radical cure of hernia appears more feasible, is probably attended with less danger, and at the same time affords a means of closing and strengthening the weakened ring, which is so desirable, and yet, with all the ingenious devices of surgery, is so difficult to attain."

——Last winter the New York Neurological Society appointed a Committee on Insane Asylum Abuses. The Committee presented a petition to the State Senate, setting forth the most flagrant abuses of the New York asylums. The Senate referred the petition to a committee of two, to take testimony. These two only took such testimony as suited them, and made a report "unfair, one-sided and grossly misrepresenting the facts," according to the opinion of the Neurological Society. This opinion seems borne out in a "Provisional Report" of the Society's Committee. The explanation offered is that one of the Senators, Mr. Goodwin, is from Utica, and is "strongly affiliated" with Dr. Gray, superintendent of the asylum there.

——Dr. J. R. Black, of Ohio, sends a note of warning, which he thinks needed, under the title, "The Drift into Solidism" (reprint from the New York *Medical Journal*). What he wants to impress on the mind of the profession is that "the transmutation or the immediate extrication of the vital energies takes rise as an immediate effect of the interaction of the blood and the tissues, quite as much in the living organism as in the inanimate machine, and not according to the method which seems to be practically accepted as true, that blood is only to build up muscle, nerve and gland tissue, from which special varieties of force are afterward evoked, through the process of waste or retrograde metamorphosis."

——The tenth thousand of Dr. John Ware's little book, entitled, "Hints to Young Men on the True Relation of the Sexes," has been printed by A. Williams & Co., Boston. In spite of those who maintain that self-abuse is attended with few or no dangers, we hold to the old doctrine that it is most injurious and in many ways; and hence we welcome the circulation of this able and pure essay, and hope for it a wide reading among young men. It was written thirty years ago, and the author is no more, but he has left a beneficent legacy of sound advice, just as much or more needed now than when he first addressed his warning words to a generation which has now reached middle life.

BOOK NOTICES.

Elements of Modern Chemistry. By Adolphe Wurtz, Professor of Chemistry of the Faculty of Medicine of Paris, etc. Translated and edited by Wm. H. Greene, M.D. With 132 illustrations. Phila., J. B. Lippincott & Co., 1879. Cloth, 8vo, pp. 687.

The author of this treatise has long been known as one of the most able chemists and successful teachers in France, and has especial celebrity for his masterly expositions of chemical philosophy, and the more abstract departments of that science. The translator has rendered the fourth edition of M. Wurtz's work with the approbation of the author, who has himself added a preface to the American edition. The field covered includes organic and inorganic chemistry, a full discussion of the atomic theory and chemical nomenclature, the alkaloids, alcohols and petroleum derivatives, and, in fact, the whole domain of the science. The numerous illustrations are carefully made and accurately printed, most of them serving to show apparatus and methods of manipulation. Indeed, no other elementary chemistry has greater claims for popularity.

One feature we note is missing which ought to be present, and that is a table of contents. Every facility ought to be furnished a student of such a difficult branch, and this is one of them. In the next edition we hope to see it remedied.

Diseases of the Intestines and Peritoneum. By John Syer Bristowe, M.D., J. R. Wardell, M.D., J. W. Bigbie, M.D., L. O. Habershon, M.D., T. B. Curling, F.R.S., and W. H. Ransom, M.D. New York, Wm. Wood & Co.

This is one of the volumes of Wood's Standard Medical Authors. As the title indicates, it is made up of a number of essays by the various English writers mentioned, extracted from Reynold's "System of Medicine" (to which no credit is given) and other sources. The usual diseases of the stomach and bowels are included, together with the peritoneum and abdominal tumors. As these essays have been before the profession many years, they need no special mention at this time.

Transactions of the Pathological Society of Phila. Volume VIII. Edited by J. Henry C. Simes, M.D., Philadelphia, 1879. J. B. Lippincott & Co.

Many instructive reports will be found in this volume, of which we have the space to mention only a few. A remarkable case of excision of four inches of the upper part of the rectum, in consequence of intussusception, caused by a villous tumor, is reported by Dr. M. O'Hara. The patient recovered promptly without a bad symptom. A case of fatty heart, with "polypus" of the right auricle, reported by Dr. T. P. Henry, is interesting for the distinction drawn by the reporter between fatty heart from atheromatous degeneration and that from primary deposit; as well as for his discussion of cardiac polypus, a mysterious affection which all who have read Rousseau's *Confessions* will remember was a prominent malady in the pathology of the last century. A well reported instance of syphilitic disease of the pleura and lungs is given by Dr. W. N. Warder. Dr. Charles H. Burnett devotes a number of pages to a discussion of the growth of the fungus aspergillus in the human ear. Recurrent or metastatic carcinoma is discussed by Dr. R. A. Cleemann. A long and thorough exposition of the causal lesions of puerperal eclampsia, by Dr. James Tyson, closes the volume.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Half-Yearly Compendium of Med. Science,	**2.50**
Reporter and Compendium, - - -	**7.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**8.25**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

POLITICO-ECONOMICAL REFLECTIONS ON THE PROFESSION OF MEDICINE.

There is a strong under current of feeling in the public, that the services of a physician ought, by rights, to be gratuitous. If we analyze this sentiment, we can probably trace it to several sources. In the first place, it appears on the surface of things that the physician's services cost him nothing. He does not give any material *quid pro quo*. The druggist furnishes the medicines, the instrument maker the apparatus. Hence, not to pay the doctor's bill does not seem like robbing him.

Another reason is, that it seems affliction enough to be sick, to lose one's time and suffer pain, without paying for that undesirable privilege. It looks like adding insult to injury for a fellow being to require you to pay him out hard cash, because you have met with unmerited misfortune.

Still stronger, perhaps, is the influence of the benevolent emotions in leading people to look grudgingly at the bill of the physician. This may seem paradoxical, but it is not. There is in every well regulated mind an instinct which prompts us to succor and relieve our fellow beings in affliction, and to do this, like the good Samaritan, without money or reward; rather, like him, besides binding the wound, to hand over from our own pockets certain pence to the innkeeper, to pay the sufferer's hotel bill. That instead of this a class of men should be found who mulct the unfortunate still further, is no doubt unconsciously repugnant to the untutored benevolent emotions.

Hence it is that many persons think themselves entitled to the gratuitous attentions of medical men, when they would not dream of asking other classes of business men to serve them for nothing. The poor of a community or a parish, those who cannot pay, are in popular opinion entitled to ask the nearest physician to visit them, and if he declines to do so on the ground that he cannot get paid, he is exposed to severe condemnation by his neighbors. All sudden accidents and emergencies demand his care, without regard to the possibility of requital. Benevolent societies expect him to look after the sick poor at their charge for nothing, or at a very low rate. Clergymen and their families are usually surprised and somewhat indignant if they are asked to pay for attendance. The families of other physicians are not supposed to be the recipients of bills.

There is, in fact, something contradictory in the business of the physician when regarded from a politico-economical standpoint. Here is a class of men depending on the presence of sickness in the community for their living, and yet ostensibly doing their utmost to prevent sickness; who profit the more the longer their customer is ill, yet who profess to be ever aiming to shorten that illness; who are engaged in the most benevolent of avocations, and yet seemingly violate the first principle of charity by demanding filthy lucre as the price of loving kindness. No wonder that there is some confusion in the public mind in view of these contradictions of theory.

Dr. RICHARDSON, of London, lately prophesied that the time will come when there will be

neither lawyers nor physicians, the need of both these professions being done away with by the increase of popular intelligence. That happy time is a long way off yet, but we are gratified that so deep a thinker has announced it as a sure thing, and the world can easily afford to wait a good while yet if it is to enjoy at last such a millennial state.

Notes and Comments.

Therapeutical Notes.

ULCERATIONS IN INFANTS.

The following is highly recommended by M. Archambault, in all kinds of painful ulcerations, etc., in infants :—

℞. Mucilage of quince seeds, 15 grams
Extract of rhatany, 5 grams.

TREATMENT OF PSORIASIS.

To clean away the scalds and prepare the skin for tarry remedies, etc., in psoriasis, nothing, says Dr. Preissmann, of Vienna, equals this :—

℞. Salicylic acid, 6 grams
Rectified alcohol, 100 grams.

Rub moderately the affected part with this mixture, on some charpie.

SACCHARINE DIABETES.

The experiments of Dr. Fürbringer, in Berlin, seem to show that the two most active agents in reducing the excretion of sugar in this disease are salicylate of soda and carbolic acid.

NIGHT COUGH OF CHILDREN.

In this affection Dr. MacDonald says, in the Edinburg *Medical Journal*, he has derived great benefit from hydrocyanic acid, prescribed as in the following mixture :—

℞. Acidi hydrocyanici dil., ♏viij
Syrupi simplicis, f. ℥ ij
Aquæ destillatæ, f. ℥ ij. M.
Fiat mist.

Sig.—One teaspoonful every four hours.

The Quinine Question.

Dr. D. J. Roberts, of Nashville, was the principal advocate, at Atlanta, of removing the duty on quinine. Shortly after the meeting the editor of this journal addressed him, asking for a synopsis of his remarks and some further light on the subject. No answer was received until after Congress had adjourned, when Dr. Roberts wrote that "it had been suggested to him by certain ones who were moving actively in the matter to use extreme caution" in his language ; in other words, to avoid a free and fair discussion of the subject.

The result of this narrow and tricky policy, quite unworthy of a liberal profession, is the passage of an Act which, as we showed last week, plays directly into the hands of foreign dealers and domestic drug sharps, and will not cheapen quinine with any certainty at all.

We hope the next movement of the kind will be engineered by men who are not afraid of honest publicity, and are above the wiles of ward politicians.

Virchow on the Germ Theory.

In his late work on "Infectious Diseases in the Army," Prof. Virchow does not anticipate much aid to diagnosis or treatment from microscopic investigations of *vibrios*, *monads*, *micrococci*, *bacteria*, etc., with reference to peculiar forms of disease. He emphasizes the fact, however, that Billroth's supposed mother plant of all these—*Coccobacteria septica*—is always present in the human body itself, notably in the intestinal canal of healthy persons ; so that a primary importation, an infection, or a transference, seems hardly required ; it is already at hand, and wants only favorable conditions for propagating and further growing.

On the Diagnosis of Large Ovarian Tumors.

Under this title Schultze contributes a short paper to No. 6 *Centralblatt für Gynäkologie*, March, 1879. The improvement in diagnosis which the author insists upon is to practice the combined exploration, with one or two fingers in the rectum and the other hand upon the lower part of the abdomen, more completely than has usually been practiced hitherto. For this purpose he recommends to chloroform the patient, and to have the tumor well pushed and held up by an assistant. This being done, its connection with the uterus and pelvis can, he says, be made out very accurately.

Western North Carolina for Consumptives.

A recent letter from a subscriber who has been spending this year in Asheville, North Carolina, adds further testimony to the value of the elevated plateau in that vicinity as a resort for phthisical patients. The district is high, well drained, dry, cool in summer, not bitterly cold in winter. The scenery is interesting and the inhabitants friendly to visitors. Dr. Gleitsmann's excellent sanatorium is near Asheville, the reports from which prove the conditions of that locality to be peculiarly favorable for consumptives.

Correspondence.

FOREIGN.

Letter from London.

Ed. Med. and Surg. Reporter:—

Trusting that a concise account of the workings of some of the most noted hospitals and medical schools of London will be of service and interest to some of your readers, I resume the subject in this letter by giving an outline of the Charing Cross College.

Among the teachers of the school is the well-known L. S. Forbes Winslow. In the college catalogue, one of the headings under the "Medical Officers" is entitled "*Chloroformists.*" This is the case, indeed, with all the English catalogues, showing that the operators, like our own much respected Prof. Gross, will have one certain one only to administer the anæsthetic.

Certain days of the week are set aside in most of the London hospitals as operation days, and these days are printed in the various medical journals, and usually a written notice is posted up in a conspicuous spot in the hospital and college, of the hour, the character of the operation, and the operator for the following or present day.

It was a matter of great surprise to find how many, even of the noted physicians, know but little of American physicians.

Making frequent inquiries, I find but very few homœopathic physicians, as compared with the United States. It is said the system flourishes best in the United States, then England and Scotland coming next, and on the Continent—its birthplace—it is decidedly scattering. Indeed, the late Madame Hahnemann said, when consulted in regard to the publication of some of her husband's manuscripts, that they must go to America; that "to America homœopathy must look for its best support and its proper promulgation."

Prof. Lister is taking well in the United Kingdom, especially in London. There is more opposition to his system in Edinburgh than elsewhere. His chief opponent in London is Dr. Hutchinson, of Cavendish Square, who is a believer in the alcoholic plan of antiseptic treatment.

There was a report going the rounds in London that Lister's practice was very small, but I am informed by a very prominent gentleman of the profession, who is personally acquainted with Mr. Lister, that this is not the case. From what he knows by personal observation, and from what the great surgeon tells him, he knows that his practice is both large and lucrative. I called at his house, but unfortunately found him away from the city for several days. He is very particular, as many other surgeons of London, about being called *Mr.* Lister, not *Dr.* Lister. The surgeon looks down upon the doctor as an inferior species of the medical class. What strange things time will work! Medical history tells us that once the surgeon belonged to a different family entirely—to the *barber tribe;* the doctors, the physicians, the great healers of human ills, would not deign to handle the knife and the various instruments of the operator. The tables are almost completely turned. The surgeon has now the maximum of medical honor, and is rather inclined to snub the plodding physician. He no longer is the barber, but the brilliant operator of the great hospital amphitheatre. Has not the brilliancy of an operation more than once dazzled a surgeon's judgment, and made him hold up exultingly a mangled foot removed, that kind nature might have restored to usefulness again?

The only sign on Lister's house is a simple brass plate, quite small, fastened to the door, having on it—"Mr. Lister." This one may read without paying a sixpence. I became so used to paying a sixpence, in London, for everything I did, that I felt almost guilty, after leaving the house, for stopping a few minutes to look at the home of this noted surgeon without dropping a coin into the hat of a near-by beggar.

Dr. Dobell gave me a very hearty reception, and made me feel at home at once. Dr. Dobell is about in midlife, looking much more like an American than an Englishman, his form being far less bulky than the ordinary run of English people.

Dr. Dobell is connected with the Consumption Hospital of London, and his chief hospital work is in the direction of heart and lung diseases. His practice is not confined to these diseases, but he is having a very good general consulting practice. He says he writes on coughs, etc., because of his hospital work furnishing so much material, and because it is very uncommon in London to report "a case in private practice," as so often is seen in American journals.

The doctor is undoubtedly right in regard to himself, but I think the British journals quite often report cases from some one's private practice.

Each arrival in a physician's office is announced by the porter dropping a card into a box, through the door of the consulting room. Hearing one drop in, the doctor slowly goes over, while conversing with you, removes the card, glances at the name and places it with others on the table. This occurred several times while I sat with Dr. Dobell. A very convenient plan, saving the inconvenience of opening the door to answer the party's knock just at a given time, when the examination of the patient may be interfered with.

C. C. V.

DOMESTIC.

Irritable Ulcer of the Rectum Treated by Forcible Dilatation.

Ed. Med. and Surg. Reporter:—

I read with interest the letter in the Reporter, volume xl, page 526, on "Irritable Ulcer of the Rectum and its Treatment by Forcible Dilatation." I have now treated six cases the past four years by this method, and with uniform success. I learned this mode of treatment from my confrere, Dr. F. A. Howe, who has for many years treated irritable fissure by Recamier's method of dilatation (Recamier, of Paris, being, if I mistake not,

the originator of this treatment). My first case resembled very much that recorded by Dr. Rush in your columns. The patient was an old lady, of seventy, who had been suffering for three months from a distressing pain in the lower bowel, occurring on defecation, and lasting for several hours. I did not dilly dally with internal remedies and topical applications, but proceeded at once to forcible dilatation, chloroform having been administered. And here I would say that I believe anæsthetics necessary to the success of the operation, for so sensitive is the anal region in this complaint that the introduction of the finger or speculum without ether is intolerable. For this reason, too, the fissure is very seldom seen by the examining surgeon, but its presence is inferred from the pathognomonic symptom—burning pain attending defecation, and lasting from one to six hours. It is, as Van Buren describes it, a dull, gnawing, excessively distressing sensation, located just within the orifice of the anus, unfitting the sufferer for any occupation, and making him completely miserable.

To return to the brief account of my first case—the operation was attended with immediate and permanent relief.

In another case which I was shortly after called in to treat, that of a young man of 27, merchant, for more than a year doomed to almost constant suffering, and seriously shattered in health, the manœuvre of forcible dilatation wrought immediate cure. I obtained considerable eclat from this case. In such cases a little skill and knowledge tells, far more than the ordinary routine practice of medicine. Here you obtain instantaneous good results, which are not so sure to follow the anxious attentions which you bestow on your fever patients.

Your correspondent has well described the mode of dilatation—the thumbs are introduced back to back, about the whole length, and then you pull them apart with about all your strength, till you hear something *snap*, or till the palmar aspect of the thumbs touches the ischial tuberosities.

The young man of whom I have just spoken had spent "hundreds of dollars," as he expressed it, "in doctoring."

My third patient was a strong, healthy man, who had for some time been disabled for work. I treated him in my office, by dilatation, without ether or chloroform. The operation was accomplished under great difficulties, and was successful, but there was an unpleasant accompaniment which made me resolve never again to perform dilatation without the needful anæsthetic.

My next patient was a consumptive, whose closing scene was rendered more comfortable by having got rid of a distressing infirmity.

The operation of Boyer—division of the mucous membrane through the centre of the ulcer, is recommended by Brodie, and is the favorite treatment of Allingham. (See the Lectures of the latter on "Diseases of the Rectum.") I have never resorted to this method. It is undoubtedly equally efficacious.

I have had two cases since the last to which allusion was made; immediate deliverance from an agony of months was obtained by the manœuvre of forcible dilatation. A good deal of soreness, smarting and swelling generally follows the operation; this needs an opiate, a cold water pad, and rest in bed for a few days.

The pathology of the affection, and the *modus operandi* of the treatment are well described in the little work of Van Buren on "Diseases of the Rectum," published by D. Appleton & Co., of New York. Dilatation paralyzes the sphincter, and gives the ulcer or fissure rest and time to heal.

In "Napheys' Surgical Therapeutics" a long list of local remedies is given, which may be tried first, before dilatation; it seems to me that the operation of forcible dilatation is so simple, so easy (with ether), so safe, and so certain, that it should supersede all other modes of treatment.

Newburyport, Mass. E. P. Hurd, M.D.

Veratrum Viride Poisoning.

Ed. Med. and Surg. Reporter:—

The fatal case of poisoning from tincture of veratrum viride, to which I drew your attention in the Reporter of the 26th of April last, was never, to my knowledge, reported anywhere, but at the solicitation of many I will endeavor to give an account of the case as it occurs to me at this time, and my friend, Dr. De Forest Willard, whom I called to assist me on this occasion, has kindly volunteered to do likewise.

The victim was an internal revenue collector, A. A., about thirty years of age, residing at D., in the vicinity of Philadelphia, Pa. I first saw him in a hotel, standing in the middle of a room, endeavoring to divest himself of his clothing preparatory to going to bed. He had the appearance of one suffering from a severe chill, but upon examination I found the skin feverish, with copious perspiration, the heart beating violently, with a corresponding weak, rapid and feeble pulse, about 120 or 130 per minute; the pupils of the eye were dilated, but responded to light; there were frequent efforts at deglutition previous to vomiting, vertigo, numbness and incoherent speech. He said that he had dyspepsia and palpitation of the heart occasionally, but he could not account for the cause of his sickness unless it was owing to four or five glasses of liquor that he had taken during the day. In answer to my inquiries as to where he had procured the liquor, it finally occurred to him that he had entered a drug store at D., which he was in the habit of frequenting, and helped himself to a *drink* of the common tincture of veratrum viride in mistake for whisky. At this startling recollection he immediately vomited profusely and was greatly prostrated. The odor of the ejected matter was sufficient to verify his statement, for the atmosphere of the apartment was strongly impregnated with the peculiar smell of the drug, also showing the immense quantity that he had taken. He also stated that after leaving the drug store he rode to the city in a wagon, a distance of five miles, entered a restaurant and partook of a hearty supper. Soon after he felt sick (vertigo), and applied for a room in a hotel, which was furnished him, and where I first saw him about two hours after he had taken the fatal potion.

The symptoms were somewhat conflicting, hav-

ing a powerful arterial sedative and a stimulant contending against each other for the mastery. While the stimulant accelerated the action of the heart the sedative diminished its force, so much so that the pulse at the wrist became almost imperceptible.

The treatment consisted in the administration of emetics, which acted promptly, until the stomach was entirely emptied of its contents, then the use of laudanum and stimulants internally and morphia sulphate hypodermically; applied warmth to the extremities, counter irritants and friction to the surface of the body; but the patient continued to lie in a semi-conscious state, showing but little response to the remedies employed. The symptoms continued to increase until death closed the scene, about 11 o'clock the same night. We resorted to artificial respiration, and continued it for some time, but all to no purpose.

It afterward appeared that Mr. A. was busily engaged during the day of the 5th November, 1872, attending to election returns (presidential election), and was greatly excited during the entire day—drinking occasionally, as he himself stated, but not to excess. It was in this state of excitement that he entered the drug store and made the mistake. We did not learn whether or not he had taken veratrum viride for palpitation of the heart at any previous time, but the inference is that he probably was in the habit of resorting to this as a remedial agent for that affection, and in the excitement had committed the fatal error. Mr. A. was a man of intelligence, and seemed to feel his case a hopeless one, as was evinced by the sudden change in his mental condition at the instant that the poisoning occurred to him, when he almost sank to the floor, after which he lay as if resigned to his fate, realizing the toxic effect of the tincture.

I am of the opinion that the drug would have acted as an emetic promptly, had it not been for the admixture of the whisky, which had previously exerted its influence on the membranes of the stomach, thereby enabling the tincture to be tolerated until an excessive quantity was absorbed into the circulation, which otherwise would have been rejected and death probably averted.

R. M. Kirk, M.D.

New Brunswick, N. J., June 27th, 1879.

NOTE BY DE F. WILLARD, M.D.

I saw the case about 10.30 P.M. The retching and vomiting had been excessive, but there was no purging. The depression was extreme, extremities cold, skin cool and clammy, and while the heart's action was tumultuous, yet the circulation was exceedingly feeble; so feeble, in fact, that the pulse at the wrist was but a faint flicker. With the ear placed at the heart, I could discover 120 contractions; the feeble wrist pulse showed not more than fifty beats. The pupils were dilated, but responded to light. Consciousness was almost obliterated, but after violent vomiting he spoke intelligibly; soon afterward, however, he sank into a state of scarcely perceptible existence, and only occasionally moaned when moved. There was no paralysis, but a decided diminution in power of muscles; so much so as to render him incapable of even sitting erect. Having been freely drinking all day, it was difficult to separate the one set of symptoms from those of the other poison; a fact which may account for the apparent incongruities of phenomena in the case.

The odor of the ejecta was very characteristic, the smell of veratrum being plainly distinguishable from that of the mingled liquor and food.

The breathing soon failing, artificial respiration was commenced, and was continued for an hour and a half, long after the heart's action had entirely ceased, for the reason that whenever the chest was fully expanded a slight inspiratory action was developed, which awakened a faint hope that life might be sustained until the virulence of the poison had expended itself, and the secretory functions succeed in carrying it away. Without this artificial help, however, there were no evidences of life after 11 P.M., and at 12.30 A.M. it was abandoned.

No post-mortem was held, but the excessive, constant vomiting, the feeble circulation, the characteristic odor, the absence of purging, the great depression, the loss of muscular power, and the manner of death, justify the belief that death was due to veratrum, and not to alcohol.

The late appearance of the symptoms shows the non-absorbent condition of a stomach when distended by a heavy meal and a large quantity of liquor. It is strange, however, that he could drive five miles in an open wagon, and then walk about the streets for nearly two hours, with a fatal dose of poison in his stomach.

1626 *Chestnut St., Phila.*

Inverted Toe Nail.

Ed. Med. and Surg. Reporter:—

Having read with interest an article by Dr Hickman, on the above subject, in the Reporter for June 14th, I thought I might contribute a mite to our knowledge of the means of curing this painful affection, that would possibly be new to some of your readers. I do not claim for it that it is superior to Dr. H.'s treatment, inasmuch as I have never seen his method applied. But I have never seen the operation of which I am about to speak fail, when thoroughly performed. The majority of the cases that form the basis of these remarks occurred in the practice of my preceptor, Dr. Samuel Holman, of North Parma, N. Y. He does not know with whom the operation originated; indeed, he has forgotten how or where he acquired his knowledge of it. I have never read any description of it, nor heard any except from him, hence I infer that it is not commonly done.

As to the value of thinning the middle of the nail, I can testify, both as patient and practitioner, having been in the habit of treating my own toe in that way, as well as of recommending it to those of my patients who are similarly afflicted. This, however, I regard as of more value in the early stages of the trouble than after the ulcerative process has begun. After ulceration has commenced, the plan taught me by Dr. Holman, and which I have successfully adopted, is simply the following: Introduce the point of a scalpel alongside and close to the root of the nail, transfix the soft parts and cut for-

ward, keeping the knife parallel with the side of the nail, until it passes out at the end of the toe. Now seize the end of the flap thus formed with a small pair of forceps; reverse the edge of the scalpel, introduce it in the wound at point of starting, and cut obliquely backward and inward (or outward, as the case may be), until the flap is removed, thus taking away the soft parts on the affected side. Dress the wound in the ordinary manner, instruct your patient to keep his nail properly cut, and not to wear a narrow-toed boot, and in a short time the cure will be effected. As the cicatrix forms it tends to retract the tissues from under the edge of the nail, thus overcoming in a measure the tendency to a recurrence of the trouble. An anæsthetic may or may not be used during the operation, as the courage of the patient and judgment of the surgeon may direct.

I have seen a patient faint while a pledget of lint or cotton was being inserted under the edge of the nail. The orthodox plan of removing the whole nail richly deserves the term "barbarous," as applied to it by Prof. Gross. The operation which I here recommend is not a severe one, and has the merit of being all done at once. If necessary to operate on both sides of the same toe, it can all be done at one sitting. I have heard patients say, on the third day after this operation, that they could get about more comfortably than for months previously. I do not wish to disparage the practice or teachings of my seniors, but simply ask for this little operation their consideration. W. D. O'Brien, M.D.

Kendall, N. Y., June 30th, 1879.

Found—A Critic!

Ed. Med. and Surg. Reporter:—

In the editorial columns of a recent number of a medical journal there is a request made for a critic, who shall see that all articles are rigidly reviewed, in order that our medical periodicals may contain less "bosh." In the editor's words I find it stated that when once some new treatment is started, the paste pot and scissors transfer the cream of the article from journal to journal, and it is translated into two or three foreign languages, and, perhaps, back again (as he has known) to the original. It is not strange that he *should* know such instances to occur, since this identical thing has occurred in the very number of his journal in which his editorial is printed. Aye, more than that, it occurs on the page opposite his editorial, and in the column and lines corresponding to his own words quoted above. It is a translation coming through the digestive track of two well-known German journals, on "Belladonna in Collapse." This translation, for which he doubtless paid, is an abstract of a long article on the subject, which was originally published in his own pages on February 2d, 1878. Alas! how soon parents forget their offspring when they have once thrust them into the world. I do not mention this fact, sir, to disparage the journal in question, which I look for with wistful eye every time it is due, but merely to answer the advertisement, which says, "Wanted—A Critic."

A Reader of Journals.

News and Miscellany.

The American Academy of Medicine

Will hold its next annual meeting in New York city, Sept. 16th. The objects of the Academy are—

1. To bring those who are alumni of collegiate, scientific, and medical schools into closer relations with each other.

2. To encourage young men to pursue regular courses of study in classical or scientific institutions before entering upon the study of medicine.

3. To extend the bounds of medical science, to elevate the profession, to relieve human suffering, and to prevent disease.

The Fellows of the Academy must be Alumni of respectable collegiate institutions, who have received therefrom—

1. The degree of Bachelor of Arts, after a systematic course of study, preparatory and collegiate.

2. The degree of Master of Arts in accordance with the usage of these institutions.

3. The degree of Doctor of Medicine, after a regular course of study, not less than three years, under the direction and instruction of preceptors and professors. They must have also had an experience of three years in the practice of medicine.

Cremation.

The Municipal Council of Udine, in Northern Italy, has lately published a decree, in which it declares that, after having duly weighed and considered the advantages and drawbacks of cremation *versus* interment, it has come to the conclusion that the former is in every respect preferable, for the following reasons: 1. In a hygienic point of view, it is undoubtedly the best way of disposing of dead bodies. 2. It is a mark of progress, because, by making cremation optional, the individual is at liberty to choose between the two modes of burial. 3. Considered from a scientific, social, religious and sentimental point of view, no valid reasons can be brought forward against it, while many very good reasons might be quoted for it. 4. The expenses would not be heavier than those of an ordinary burial. Cremation has been long introduced, and is carried out, at Milan, as at Gotha. It is now also officially authorized in Paris. We shall be glad to welcome it in Philadelphia.

The Yellow Fever Again.

With great regret we make the announcement that the yellow fever, in epidemic form, has broken out again in the city of Memphis. The first cases were reported on the 10th inst., during the great heats of July, and as fully three months from that date must elapse before the appearance of frost, we cannot but look forward with gloomy forebodings to this summer in the lower Mississippi valley. The powers conferred upon the National Board of Health may succeed in stemming the progress of the epidemic, and no doubt will material lessen its ravages. But when it is

remembered that this is more than a month earlier than the outbreak of the disease in Memphis last year, the prospect, at best, is a dark one.

It is probable that the Board of Health of Memphis has done the most it could do in preparing the city to resist the fever; but with a bankrupt municipality, and the accumulations of forty years of neglect and disregard of sanitary precautions, with streets without sewers and paved with rotting wooden blocks, the task was herculean. At last accounts all were leaving who could, and this is much the safest precaution to take.

We also notice that an official telegram from Lisbon, dated June 24th, announces the appearance of two cases of yellow fever at Pedrouso, a village situated about three miles from Lisbon.

The Hahnemann Medical College

Of Chicago was charged before the Illinois State Board of Health with issuing diplomas to persons who had not attended two full courses of lectures at the college. These charges were, moreover, amply proved, and finally acknowledged. Yet, on the ground of the "doctrine of equivalents," and of "testimonials," as many of which were produced as is necessary to start a quack medicine, the Board concluded by affirming the good standing of the College. This is one of the weakest acts we have yet heard of about that Board.

Personal.

—The degree of M.D., *honoris causâ*, was publicly conferred on Prof. Lister, by the University of Dublin, on June 26th.

—Doctors Schneider and Smith, of the Cleveland medical faculty, have been fined $500 each and costs, and the Janitor $250 and costs, for concealing the body of the late Edwin French.

—Dr. H. R. Storer, the well-known gynæcologist, who formerly resided in Boston, but who now lives at Newport, Rhode Island, was, on the 8th of June, baptized into the Roman Catholic Church.

—Dr. Neubauer, the well-known joint author with Professor Vogel of "An Introduction to the Qualitative and Quantitative Analysis of the Urine," a work translated in 1863 for the New Sydenham Society, and recently republished in this country, died at Wiesbaden on June 2.

Items.

—The Paris initiative committee for the consideration of a proposal to enforce a diminution of the hours of labor in factories from twelve to ten hours, has decided in favor of the latter.

—At a meeting of the Butler Co., Iowa, Medical society, the following officers were elected for the coming year: President, Dr. Spooner; Vice President, Turner; Secretary, Boucher; Treasurer, Isherwood; Censors, Dudley, Young and Powers.

—Two first-class British ocean steamships are now plying between Baltimore and Halifax, for lack of anything better to do, to give invalids and tourists a cheap and brief ocean trip, with all the belongings of a regular passage over the Atlantic.

—The members of the medical profession in Berlin have established, in commemoration of the Emperor's golden wedding, a fund for the benefit of distressed members of the profession in that city, and their widows and orphans. The capital sum contributed was about $3000.

MARRIAGES.

BIDDLE—McKENNAN.—On Thursday, June 19th, at Trinity Church, Washington, Washington county, Pa., by the Rev. Dr. Earp, Alexander Williams Biddle, M.D., of Philadelphia, and Annie, daughter of the Hon. William McKennan, Judge of the United States Circuit Court of Pennsylvania.

GREEN—BURK.—June 11th, 1879, by Friends' ceremony, G. D. Green, M.D., of Media, and Annie Warner Burk, of Philadelphia.

HOFF—ATLEE.—On the 17th ult., in St. Mark's Church, this city, by the Rev. E. A. Hoffman, D.D., George A. Hoff, of Waterloo, Iowa, and Margaret H., youngest daughter of the late Washington L. Atlee, M.D.

HOWELL—KNOX.—June 5th, 1879, in Freeport, Harrison County, O., by Rev. M. C. Grimes, assisted by Rev. J. K. Grimes, Dr. J. G. Howell and Miss Mary J. Knox, both of Freeport, O.

LACY—KLINE.—On the 29th of May, 1879, in Grace P. E. Church, by the Rev. Dr. Suddards, assisted by the Rev. Mr. Ashton, Fred. C. Lacy, of Allegheny City, Pa., and Lillian A., daughter of Dr. R. H. Kline, of Philadelphia.

LENKER—STODDART.—At Wilkesbarre, Pa., June 5th, by Rev. F. B. Hodge, Christain Lenker, M.D., of Columbia County, Pa., and Mary, daughter of the late John Stoddart, Esq., of Wilkesbarre.

LEVY—PALMER.—At Grace Church, Orange, N. J., on Tuesday, the 10th inst., by the Rev. James S. Bush, of West Brighton, Staten Island, assisted by the Rev. Dr. Schuyler, Rector of the Parish, Dr. Frederick Arthur Levy and Margaret I. Reynolds, daughter of the late Hunloke W. Palmer.

MURDOCK—DILLINGHAM.—In this city, on the 26th ult., by the Rev. Dr. George Dana Boardman assisted by Rev. Dr. J. N. Murdock, Annie, daughter of Dr. S. Dillingham, and Joseph B. Murdock, U. S. Navy.

NEFF—LUDLOW.—On the 12th inst., by Rev. J. A. Henry, D.D., Dr. Joseph S. Neff and Miss Hattie L. Ludlow, both of Philadelphia.

PURSELL—BARTOLETTE.—In Milford, N. J., June 4th, by Rev. Isaac M. Patterson, Howard Pursell, M.D., of Bristol, Pa., and Nellie C., daughter of the late Charles Bartolette, M.D., of Milford.

RANKIN—SERVIS.—June 5th, by Rev. J. S. Beekman, R. M. Rankin, M.D., of Hopewell, N. J., and Miss Laura S. Servis, of Reaville, Hunterdon Co., N. J.

RUSHMORE—HAFF.—On Wednesday, June 4th, 1879, at the residence of the bride's parents, Hempstead, Long Island, by the Rev. Charles E. Miller, Edwin C. Rushmore, M.D., and Mary Ella, daughter of Benjamin A. Haff, Esq.

SABINE—BARDWELL.—In Newport, Vt., June 11th, by Rev. E. E. P. Abbott, Dr. Silas A. Sabine and Clara A. Bardwell, both of Claremont, Vt.

VANUXEM—PFEIFFER.—At Camden, N. J., in the Second Presbyterian Church, June 19th, by Rev. L. C. Baker, Henry Vanuxem and Marie, daughter of G. S. F. Pfeiffer, M.D., all of Camden.

WOODS—HUNTZINGER.—In this city, on the 19th ultimo, by the Rev. A. W. Williams, Dr. Matthew Woods and Emily L. Huntzinger, both of this city.

WOOLSEY—CUNNINGHAM.—On the evening of April 13th, by Rev. L. B. Hughes, M.D., at the parsonage of Twenty-eighth Street M. E. Church, No. 1218 N. Twenty-seventh Street, William F. Woolsey, M.D., and Miss Mary Cunningham, both of Philadelphia.

DOCTOR RABUTEAU'S

(Laureate of the Institute of France.)

DRAGEES, ELIXIR & SYRUP

Of Proto-Chloride of Iron.

"The experiments made in the hospitals of Paris have demonstrated that *Dr. Rabuteau's Dragees, Elixir and Syrup* regenerate the red globules of the blood with a rapidity never observed with the use of the other ferruginous preparations. These results have been proved by the various *Compt-Globules.*

"The ferruginous preparations of *Dr. Rabuteau* do not cause any constipation, and are perfectly tolerated by the weakest persons."—*Gazette des Hospitaux.*

Dr. Rabuteau's Elixir is prescribed when some difficulty is experienced in swallowing the Dragees; it is especially adapted to weak persons, whose digestive functions need strengthening or stimulating.

Dr. Rabuteau's Syrup is especially prepared for children, who take it readily, because of its agreeable taste.

MEYNET'S

DRAGEES OF COD-LIVER EXTRACT.

Careful experiments have established the fact that the **EXTRACT OF COD LIVERS** contains very valuable properties, which render it superior to the ordinary cod-liver oil. It is composed principally of *Gaduine*, large proportions of *Iodides, Chlorides, Bromides, Phosphoric Acid, Lime, Soda* and *Ammonia*, and especially *Propylamin*, all of which enter, but in very small proportions, into cod-liver oil.

These dragees of pure cod-liver extract take the place of cod-liver oil, and have been used with eminent success by medical celebrities of Europe in cases of *Scrofula, Rheumatic Affections, Rachitism, Phthisis*, and in all cases where a propylamic medication is indicated.

MEYNET'S DRAGEES are sold in bottles containing 100 dragees. Dose, 2 to 6 a day. Each dragee is equivalent to two tablespoonfuls of cod-liver oil.

MEYNET'S GRAINS are small granules intended for children. 10 are equivalent to 1 dragee.

E. FOUGERA & CO., New York, Agents for the U. S.

RIGOLLOT'S MUSTARD PAPER.

Is one of the most important and useful discoveries of the age, but it is not (as certain dealers of bad faith pretend) a preparation that any one can make, for it is not manufactured with a mustard that every one can buy.

RIGOLLOT'S MUSTARD PAPER.

Is the invention of Mr. P. RIGOLLOT, who is the exclusive owner; it is the only preparation which has been adopted by the civil and military hospitals and the armies and navies of France and England, and which has obtained a medal at the Centennial Exposition at Philadelphia. All other mustard plasters or leaves of whatever name, are but imitations of the original

RIGOLLOT'S MUSTARD PAPER.

Physicians will find it the most reliable sinapism, prompt and certain in its action, and will therefore always prescribe it. Every sheet in order to be genuine must bear the annexed signature of the inventor,

Sold in tin boxes containing 10 sheets, also 25 and 100 sheets, by all respectable chemists throughout the world.

E. FOUGERA & CO., Agents,

NEW YORK.

PHOSPHOROLE.

PHOSPHORUS and COD-LIVER OIL

have now an established position throughout the civilized world as important therapeutical agents. A *perfect combination* of the two has long been a desideratum, since they are both of value in the same disorders, while the cases in which one is demanded and the other contra-indicated are exceedingly rare.

The combination in PHOSPHOROLE has the twofold advantage of furnishing *the best possible form* for the administration of *phosphorus*, and *a more effective form* for the administration of *cod-liver oil*.

With regard to the former, it has been decided by the highest chemical and medical authorities that *phosphorus* should be administered *in a free state*, and in a vehicle which ensures its *perfect diffusion*, its *absolute unalterability*, and, as far as possible, its *prompt assimilation* without the gastric irritation to which the ordinary methods of exhibiting the agent give rise. It is well known that pills, emulsions, solutions in ether, chloroform, vegetable oils and resin, etc., have all failed to fulfill one or more of these conditions. Even an ordinary solution of phosphorus in cod-liver oil would not answer the purpose in all respects. We claim, however, that PHOSPHOROLE completely satisfies all the conditions. From the method of preparing it, in an atmosphere of dry carbonic acid, the phosphorus is *entirely dissolved without oxidation*, and by our mode of manipulation *a positive uniformity of strength* is ensured. It is then promptly bottled and sealed, and its *stability and permanence* thus secured. The exact amount of phosphorus in each dose is known, its efficiency is ensured, and the irritant effects upon the stomach are reduced to a minimum by the blandness of the oil. As a means then of administering *phosphorus* in the many cases in which it is indicated as a *nervous tonic and stimulant*, it is claimed that PHOSPHOROLE is the best attainable in the present state of our knowledge.

The value of *cod-liver oil* in phthisis is so familiar to the physician that it is needless to dwell upon it. But the value of *phosphorus* is also universally recognized in this disease, especially when complicated with nervous derangements. The *combination* of the two therefore furnishes a more effective form for the administration of cod-liver oil in the great majority of cases in which that remedy is indicated, and one which will at once commend itself to the profession.

A dose of two teaspoonfuls of PHOSPHOROLE contains $\frac{1}{100}$ of a grain of phosphorus. This dose, when given after a meal, is effective, and not very liable to interfere with digestion. *Phosphorus is cumulative in its action, and should be administered with watchful care.* About $\frac{1}{12}$ grain is considered the largest safe dose, and we rarely need go higher than $\frac{1}{20}$ or $\frac{1}{30}$ of a grain. At the very first appearance of the smallest gastric derangement, the exhibition of phosphorus should be stopped.

PHOSPHOROLE is handsomely put up in pint bottles only, and may be obtained at all first-class druggists throughout the United States.

Descriptive Circulars furnished upon application.

SECOND EDITION

OF

DR. L. TURNBULL'S

MANUAL OF ANÆSTHETIC AGENTS,

And their Employment in the Treatment of Disease,

With 322 Pages and 27 Illustrations.

PRICE $1.50.

A new table of 8 extra pages of deaths from chloroform will be found of especial interest and great importance to the medical and dental professions.

"The book is well written, and the author, while consulting everything of importance, and giving due credit to the work of others, has, at the same time, furnished a large amount of original material, which adds greatly to the value of the work. The book certainly deserves well of the profession."—*Boston Medical and Surgical Journal.*

"This volume should not only find a place in the library of every practitioner who administers anæsthetics, but many of its facts, cautions and directions should be carefully pondered and remembered."—*The Dental Cosmos* (Philadelphia).

LINDSAY & BLAKISTON, Publishers,
25 South Sixth St., Phila.

On receipt of the price, the work will be sent, postpaid, from this office.

HOSPITALS, DISPENSARIES, PHYSICIANS, DENTISTS, DRUGGISTS, PHOTOGRAPHERS, ETC., ETC.

The article furnished by us will be found superior to any other, on account of the facilities we possess for the manufacture, and the care taken at every step of the process.

Not only in general surgery, but especially in gynæcological practice, Absorbent Cotton has found great favor. It differs little from ordinary cotton in appearance, except in its uniformly fine quality and pure white color, freedom from all impurities — being entirely cleansed from oil, resin and all foreign matter.

The property of instantly absorbing liquids, its exquisite softness and great cheapness render it an invaluable substitute for Patent Lint, Charpie or Sponge.

We put up our Absorbent Cotton in neat and convenient packages, containing one pound, one-quarter pound, and two ounces.

A descriptive Circular will be forwarded on application. Samples containing two ounces will be sent, free of postage, on receipt of twenty cents.

PEPTONIC PILLS.

Pepsin, Pancreatin with Lacto-Phosphate of Lime and Lactic Acid.

(COPYRIGHT SECURED.)

This pill will give immediate relief in many forms of Dyspepsia and Indigestion, and will prove of permanent benefit in all cases of enfeebled digestion, produced from want of proper secretion of the Gastric Juice. By supplementing the action of the stomach, and rendering the food capable of assimilation, they enable the organ to recover its healthy tone, and thus permanent relief is afforded. One great advantage of the mode of preparation of these pills is the absence of sugar, which is present in all the ordinary Pepsin and Pancreatic compounds. In this form, the dose is much smaller, more pleasant to take, and is less apt to offend the already weak and irritable stomach. The results of their use have been so absolutely satisfactory, that we are confident further trial will secure for them the cordial approval of the Medical Profession and the favor of the general public.

Each pill contains one grain of pure PANCREATIN, which is equivalent to 10 grains of the ordinary or Saccharated usually prescribed and dispensed. Physicians will appreciate the great advantage of this mode of administration, the increased benefit to the dyspeptic being due to a full and effective dose of each, freed from unnecessary bulk, and really hurtful addition of sugar. A single pill will give immediate relief.

DIRECTIONS:—Take one pill immediately after eating or when suffering from Indigestion, Lump in the Throat or Flatulence. For children, reduce the pill to powder and give one-fourth or half, according to age.

THE ANTISEPTIC TREATMENT OF WOUNDS.

BY GEORGE HALSTED BOYLAND, A.M., M.D.

(*Concluded from Vol. xxxix. p.* 336.)

The addition of almond oil in solution with carbolic acid (1 : 10) is advocated by Prof. Neudörfer, who prefers, instead of lint or charpie, undressed calico dipped in this and spread over the entire surface of the wound; he speaks also of catgut, used as a ligature, and left to heal in the wound. We are prepared, with him, to believe that the catgut in the human body dissolves, and thus possesses an advantage over all other ligatures. The salicylic acid and benzoic acid dressings occupy second and third places with Neudörfer, who has further employed as a dressing sugar, also in form of syrup, and with not unfavorable results. In his opinion the open treatment of wounds cannot compete with the antiseptic method, as the first has relatively circumscribed limits, does not allow prima intentio, and is in itself not sufficient for cicatrization, for which it is rather necessary to bring on other means; moreover, the time required in healing is longer; on the other hand, it is admitted that the open treatment of wounds is simpler, and that pyæmia, septicæmia and nosocomial gangrene do not occur. Certainly, there are cases in which the open treatment is impossible. The question as to whether germs or particles floating in the air would not be more likely to settle in a wound thus treated might be discussed with a view to ascertain whether it is best to use such a method at all or not.

Experience and our own judgment must be the guides as to what method to employ in the treatment of wounds in general. Such treatment ought, of course, to vary according to the nature of the case presented. It will be found that certain small wounds and ulcers, for instance, unimportant cuts or abrasions, some varieties of herpes, heal best and quickest when absolutely left to themselves; it being evident with such that the germs or particles floating in the air, even though foul, are caught in the serum, which becomes thickened and forms a crust, now protecting the wound; because the surface is so small and the septic molecules so minimal that they are comparatively harmless.

As to the treatment of larger wounds (and here we consider only clean cut wounds, even edged wounds, such as are made by knives), the most successful plan will perhaps be found in uniting the edges with adhesive plaster, placing a suture or two, or as many as may be necessary, first, and over the plaster a dry compress, held in place by a roller bandage. If the patient complains, after several hours, of burning, let him or her take a sponge wet with cold water, and squeeze it for a few minutes above the bandages, in such a manner that the water will trickle down under them. There is nothing that relieves the sensation of burning, under such circumstances, quicker than cold water without any ingredient whatever. Spring water is preferable when it can be obtained conveniently and fresh.

The third class of wounds, embracing all large irregular wounds, from a variety of causes, such as compound fractures, wounds from boiler explosions, bites from animals, etc., should, without doubt, all be treated on the antiseptic principle,

varying the method according to the nature of the wound. Enough proof has been adduced to establish the advantage to be derived from pursuing this course. Whatever treatment we employ, whether it be the so-called open treatment or the treatment by occlusion with adhesive plaster, bandages and cold water, or the antiseptic method, this rule should be observed: "*that the simpler the dressing the better the result; with one good antiseptic and cleanliness we accomplish all.*" (Page 114, "Antiseptic Treatment of Wounds," Boyland.) The compound antiseptic dressing briefly mentioned in this article gains us nothing more, and throws us into doubt as to which of the two antiseptics employed is the most effectual, or as to whether both are equally so, thereby making their intensity double, and influencing thus both the wound surface and the time required in healing. Again, have we antagonism or synergy? One thing we certainly do not possess, and that is, much experience, practical or literary, in the compound antiseptic treatment of wounds. With reference to the technic of the treatment in question, not only Lister himself, but many of his followers, have altered much. In the first place, Thiersch has obtained good results by substituting salicylic for carbolic acid. Thus far his innovation has found few adherents, and some surgeons, for example, Bardeleben, of Berlin, have thrown aside salicylate. The simplest modification of Lister's bandage was introduced by Bardeleben, and consists in carboljute. Boric acid and benzoic acid have, until the present moment, been too little employed in surgery to estimate their value. In oncotomy and compound fractures the antiseptic method is very favorable; also in diseases of the joints, which we can incise more boldly than formerly; in amputations it seems to procure for the patient a better stump than either of the other methods, and the prima intentio is an advantage by no means to be undervalued. Of especial importance are, further, the spray, the catgut ligature and the drainage. We prefer the system of drainage by counter openings, and Chassaignac's caoutchouc tube, being more pliable, better for the granulating surface and more agreeable to the patient, than his silver tube. Finally, it must be admitted that Lister's method has gained more and more ground, and has more intellectual support than opposition; notably, of late, have German surgeons done much to enlarge upon the method and bring it into general practice. The antiseptic treatment of wounds is a great advance in practical surgery, whether the theory upon which it is based be right or not; if, still further, able to hinder secondary (so-called accidental) wound diseases, it is perhaps the greatest.

This antiseptic treatment can be easily employed in private practice, where it will be found very efficacious; but the hospital is the place where it benefits most, and where it diminishes in a great degree the danger of infection among surgeons and nurses. But a few of the best known and most employed antiseptics have been selected, merely as types of a large class, in choosing from which the surgeon must be guided by his own judgment and experience.

REMOVAL OF A FIBRO-CELLULAR TUMOR FROM THE LEFT CAROTID TRIANGLE.

BY N. B. KENNEDY, M.D.,
Of Hillsboro, Texas.

On the morning of the 29th of May, 1879, I was called thirteen miles into the country, to remove a tumor from the neck of Joe Doyle, a young man, twenty-six years of age, of thin habit, small size, and of a nervo-bilious temperament. On inquiry, I learned his health had always been good, and none of his ancestry had ever had a tumor of any kind.

On examination I found a tumor about the size of a hen egg occupying the apex of the left carotid triangle. I diagnosed it to be of a glandular or adenoid variety. A small tumor about the size of a split pea was in front of the thyroid gland, and another about as large in the epigastric region.

From the patient I obtained the following history: About four months since he noticed a growth in the carotid triangle. It was quite small, and as it gave him no pain, he paid very little attention to it. About two weeks afterward he noticed the others mentioned. The tumor in the carotid triangle grew rapidly. Three or four weeks ago he began to suffer excruciating pains, especially at night, so much so as to deprive him of sleep. There was also hemiplegia of the whole of the left side, accompanied with peculiar sharp, lancinating pain, worse along the course of the femoral nerve. He now sent for two physicians, who immediately commenced to apply rubefacients and resolvents, with the hope of dispersing the tumor, but in vain.

He now sent for me, as a last resort, to come and remove the tumor. I would remark in passing, in my experience excision is the only remedy for glandular or fibro-cellular tumors;

and they very seldom recur after excision. While excision is the only remedy, it should never be done when the tumor is growing slowly, is not producing pain from nerve pressure and is not in a position to disfigure the patient. The patient, being placed upon his back on a single bedstead, upon a mattress, between two doors (where he could obtain fresh air), with the head turned to the right side so as to put the anterior border of the sterno-cleido-mastoid muscle upon the stretch, I proceeded with the operation.

Dr. Finch, a physician living near, kindly assisting me, gave the anæsthetic, chloric-ether, which I beg leave to state here I have used in hundreds of cases without any fatal effects, and I think it by far the safest anæsthetic we can use. The patient now being fully under its influence, I proceeded by making an incision over the tumor in a line with the anterior border of the sterno-cleido-mastoid muscle, about two inches and one-half in length, through the skin and cellular tissue, severing several small superficial arteries, which I twisted; I then made a transverse cut at right angles to the first, thus completing a crucial incision. After exposing the capsule of the tumor, I endeavored to enucleate it with my finger, but failing in this, I resorted to the handle of my scalpel, but finding the tumor bound down by very firm bands of adhesive fibre, I was forced very slowly and carefully to dissect the tumor out, severing a number of small arteries, one of which I was compelled to ligate. After dissecting the tumor down on both sides and wiping away all blood, I could see the sheath of the carotid artery, and I knew, by the great resistance met with in trying to tear the tumor away, that it was attached to the artery. I therefore pared away the tumor from the artery, cutting as near as I dared, and then applied pure carbolic acid to the small portion remaining attached. I then sponged out the wound with a ten per. cent solution of carbolic acid, and in a short time had the satisfaction of seeing all venous oozing cease.

Before closing the wound I called the attention of Dr. Finch to one of the prettiest views of the great vessels lying in the carotid triangle it has ever been my pleasure to behold in the living subject, consisting of the descendens noni nerve in front of the carotid artery, and the artery behind the nerve, and the internal jugular vein, external to the artery, and by pushing the artery to one side, the vagus nerve.

The wound was brought together by two interrupted sutures, and carbolized lotions applied. The patient reacted promptly from the anæsthetic.

The tumor proved to be internally of fibrous tissue and externally of cellular tissue. It weighed nearly half a pound, and was of a very firm texture. The patient did well.

In conclusion, I would repeat, and especially urge upon young surgeons, never to remove a tumor when it is growing slowly, and which is not producing any nerve pressure, and not so situated upon the body as to produce deformity.

THE GERM THEORY AND DISEASE GERMS.

BY CHARLES T. REBER, M.D.,
Of Shelbyville, Ill.

Puerperal fever, erysipelas, some forms of pneumonia, scarlatina, diphtheria, "milk sickness" and a few others among the constitutional diseases are now reasonably proven to be caused by disease germs. They are recognized as infectious diseases. The germs that cause these diseases can reproduce themselves, and to an unlimited extent. There is an endless multiplication of living organisms. One of the most striking characteristics of infectious diseases is their specificness, as shown by the fact that always, and under all circumstances, a given disease is solely due to a given kind of morbid agent or cause. When infection has taken place the specific disease is certain to follow, and it is uniform and unvarying in its symptoms and in its course. Diseases produced by disease germs have as complete correlation between cause and manifestation as there is in poisoning with chemical agents.

There are no such positive and uniform effects, no such constancy in the relations between cause and manifestations, in the so-called malarial and other diseases. Exposure to the same degree of cold will cause various affections, according to the individuality of the persons attacked; one person may have a tonsillitis, another bronchitis or pleurisy, diarrhœa, toothache, rheumatism or many other affections. The same is true in regard to the so-called malarial diseases. Exposure to the same cause produces in one a periodic frontal neuralgia, in another a facial paralysis, syncope, periodic emesis or diarrhœa, dysentery, enlargement of the thyroid, liver or spleen, epistaxis, palpitation, or other derangements of the heart's action, asphyxia, jaundice, intermittent, remittent and other forms of fever, or one of many other diseases. In the manifestations produced by this cause there is no uniformity, nothing specific, in incubation, attack, course, or any other character or aspect. The manifesta-

tions from the so-called malaria have no specific character, any more than those which result from undue exposure to cold, or than those that result from the violation of the general laws of health. Neither are the products, secretions, blood, nor any of the constituents of the body of a patient sick with a so-called malarial disease infectious or contagious, nor do they become so upon exposure to the atmosphere, under any circumstances. We can understand that if gemiasma, biolysis typhoides, or any similar germ, be the cause of a contagious fever, the germs may make their escape from the body through one or other outlet, the surrounding atmosphere becomes contaminated, and that persons exposed are liable to be attacked by the same disease. But if so-called malarious diseases are caused by similar organisms, what becomes of the germs? They must leave the patient or he could not recover. They do not infect the atmosphere or the clothes of the patient, or the disease would be spread by them.

"If, after reproducing itself to such a marvelous extent within the body, the whole mass of vegetation, plant and germ, parent and offspring, suddenly ceases to exist, what puts an end to its life? and what becomes of the debris?"

"Again, if, after passing through the human body, these germs be incapable of reproducing themselves, they must necessarily exist independently in the atmosphere of every malarious locality; they must, therefore, in hot climates, thrive in marshes and swamps, in parched, sandy deserts, and upon barren rocks; they must flourish and be in their fullest vigor when the air, as well as the earth, is perfectly dry and parched, and all perceptible vegetation is burned up, and also when both the soil and the atmosphere are saturated with moisture, and scoured by tropical rains; the winds blowing down from snow-clad mountains too, must be loaded with these germs, as they often bring malaria in their train. And yet, in temperate climates the same vegetations must be confined to the vicinity of marshes."

The so-called malarial diseases have nothing specific in their nature. Therefore, they are not caused by a specific or infectious cause. All disease germs produce specific infectious diseases. Consequently, the so-called malarious diseases should not be classed among infectious diseases. There is no such disease as a miasmatic infectious disease in contradistinction from any other infectious disease.

As far as my knowledge extends, no author of a text book on the practice of medicine endorses the doctrine that malarial diseases are produced by disease germs.

IODIDE AND BROMIDE OF POTASSIUM IN ALBUMINURIA.

BY J. W. COMPTON, M.D.,
Of Evansville, Ind.

Many good remedies may have a much wider range of therapeutic usefulness than is usually accorded them. The iodide of potassium has for the past ten years, in my hands, exhibited well-marked good effects in the treatment of albuminous nephritis.

In 1869 E. S., age thirty-five, presented himself to me for treatment for a chronic renal trouble. At this time he exhibited well-marked œdema; much swelling from effusion in the cellular tissues, particularly of the lower limbs and face. Obtaining some of his urine, and submitting it to the usual tests of heat and nitric acid, it became almost solid albumen, and having but slight hope of anything more than mere temporary relief from the ordinary course of diuretics recommended in such cases, and having my attention about this time called to the successful treatment of Bright's disease by iodide of potassium, I determined to try this old remedy in a new rôle.

The patient was directed to take, in solution, ten grains iodide of potassium four times per day, and to increase this dose daily, up to the largest amount tolerated by the stomach and mucous membranes. The patient proved to be a good subject for the free administration of the remedy. The quantity taken per day was gradually increased, until it reached the unusual amount of three drachms daily, and before he ceased taking the remedy he informs me that the renewals of the prescription had cost him over one hundred dollars. These large doses brought out, to almost a troublesome extent, the characteristic red eruption on the skin, particularly on the lower extremities. At this stage I had the pleasure of seeing the dropsical effusion disappear, and the patient restored to perfect health. He is an active business man to-day, and his recovery can, with much certainty, be traced to the remedy in question, as he took no other medicine during the time. For the first year or two he had occasional returns of swellings of the extremities, which were in a short time relieved by resorting again to the remedy.

More recently there appeared under my observation similar good results from the administration of bromide of potassium in albuminous urine. Bromide of potassium possesses alterative and resolvent properties similar to those of the iodide, and in many forms of disease complicated with albuminuria will be found preferable

to its congener. In addition to its acknowledged strong eliminative powers, it possesses physiological properties similar to those of other potassium salts; yet its action on the nervous system and upon the circulation are so far diverse as to give to it some entirely different therapeutic properties. Its quieting control over cerebral excitement, and under certain forms of nervous excitement constituting unrest and other forms of nervous derangement, often render it a valuable substitute for the iodide. These various forms of nervous conditions are familiar to the profession, need not be repeated here, and not wishing to occupy space unnecessarily, I deem it quite sufficient to call the attention of practitioners of medicine to the therapeutic indications of two valuable agents in the treatment of a disease in which I am led to believe these remedies are not generally administered, and which so frequently baffles our best efforts as to make it desirable for us to have access to all therapeutic agents that promise permanent benefit.

FRACTURE OF SKULL, WITH DEPRESSION—REMOVAL, WITH COMPLETE RECOVERY.

BY E. W. RUSH, M. D.,
Of Paris, Texas.

On the 2d of August, 1878, Oscar Anderson, aged eight years and three months, was thrown from a wagon drawn by two horses, that became frightened at the street cars, his head striking the railroad track. The little fellow was at once picked up and brought to my office (opposite the place of accident). There was considerable shock, but the smelling bottle and a dose of brandy was equal to the emergency. After this my attention was directed to the hemorrhage. From the character of the blood I was satisfied that it came from the middle meningeal artery. On examination I found, situated over the left side of the parietal bone, a very small incised wound, half an inch in length, through the scalp, laying bare the skull, my probe revealing a fracture of uncertain solution; therefore, after shaving the hair from the scalp, I enlarged the wound and exposed the seat of depression. Dr. Hooks was now called to see the case with me. After examination, the operation of trephining was determined upon.

At 4 P.M., after reaction had been fairly established, we proceeded to operate, assisted by Drs. Hooks, Fort and others. An anæsthetic was given, the incision was enlarged, in shape of the letter Y, thus revealing the extent of injury. We removed, by the aid of a hook and elevator, a depressed bone, elliptical in shape, two inches in length by one inch in width, running at an oblique angle from the parietal to the occipital bones, crossing the lambdoid suture at its left half. The detachments were composed of about one-quarter of the occipital and three-quarters of the parietal bones. Besides this there were two other smaller pieces, that were driven downward and upward (on the corresponding sides of the fracture), under the parietal bone, that required great care to remove, and then not until a piece from above was taken away by the saw. These spicula of bone were each about one inch square, and of a finger nail shape, thus wounding the membranes as well as the brain itself, as was evinced by the escape of the latter. We also believe that they did the mischief to the meningeal artery that occasioned so much hemorrhage in the onset of the accident. The fracture did not stop here, as was at first presumed, but a rent continued its course quite through the parietal, to the squamous suture of the temporal bone; in all, making the extent of fracture some five inches in length. After the hemorrhage ceased the parts were cleansed with weak carbolated water, the scalp adjusted, and secured by six interrupted silk sutures, afterward supported by a cold compress and roller, the little fellow was comfortably placed upon a cot in one room of my office, the recumbent position strictly enjoined. I am indebted to several ladies (a corps of intelligent nurses), who volunteered their services in this case, and doubtless by their care and attention, bestowed by day as well as by night, greatly assisted in restoring this little sufferer. Ice bags were freely used around the head, carbolated ice water over the seat of the wound. Bromide of potass. and tinct. digitalis, in appropriate doses, were relied upon to control the nervous excitement; drastic cathartics, as a derivative to the brain; those preferred in this case were, ext. podophyllin, colocynth, pulvis. jalap, judiciously combined and made into powders. Dose, one to be given every night. Alimentation the mildest, such as milk, cold broths, etc., taken in small quantities and often. This was our general plan of treatment, which continued for several weeks, but the little patient convalesced, and the stitches were removed from the wound, on the tenth day. The greater part of the wound had healed by first intention; the remainder was treated by carbolized oil dressings, and supported by adhesive plaster strips. Subsequently to the operation his temperature never exceeded 100; his mind remained intact (he was a very sprightly

lad, and manifested great concern in getting well); there was not the least untoward symptom observed in the after treatment, all of which tended to a speedy and complete recovery.

What conclusions should be drawn from this case? Was all this kindness due to a thorough depletion from the meningeal artery at the outset? And what are the probabilities of future derangement, either by non-closure or redevelopment of bone?

ASPARAGIN.

BY MARY J. MATLACK, M.D.,
Of Raleigh, W. Va.

Asparagus is well known as an indigenous plant in Europe, and one largely cultivated there and in America as an article of food, the young shoots being the part of the plant used. Some attention has been given to its medicinal properties and uses. As a remedy, both the shoots and roots are employed, from which a tincture or syrup is prepared; there is also an active principle, asparagin, obtained from the juice of the plant. It acts as a sedative, reduces the heart's action, and has been of service in cases of hypertrophy of the heart and other diseases of that organ, attended with excessive action. I have prescribed it in cases of headache, where there is a sense of fullness of the eyes and general congestion experienced, with satisfactory results. Its leading virtue, however, is a diuretic; it imparts its characteristic odor to the urine, and causes copious diuresis. Asparagin is obtained from the plant by the process of dialysis, and is particularly serviceable in hypertrophy of the heart. I have found the following formula of intrinsic value:—

℞.	Asparagin,	grs.x	
	Bromide potass.,	ʒij	
	Sacch. alb.,	ʒiij.	M.

Sig.—Make ten powders, one thrice daily.

In dropsy dependent on disease of the heart it is one of the best remedies, given in doses of one grain three times a day. In lithic acid diathesis and chronic gout it is especially indicated. Its primary action, in doses of from one to five grains, is powerful in quieting the function of the brain and spinal cord, and nervous irritation generally; its secondary action is upon the blood, as a depurant, stimulating the skin, kidneys and serous tissue of the bowels. In this way it becomes a valuable alterative and diuretic. As your journal is a widely read medium, these few remarks on the remedy may be acceptable to the profession through its pages.

Medical Societies.

COLLEGE OF PHYSICIANS AND SURGEONS, PHILADELPHIA.

At the regular meeting in May a paper on

Recoveries from Mental Disease

was read by Dr. Isaac Ray. He said:—

Respecting the curability of insanity, a wide difference of opinion has always existed, and notwithstanding the improvements made of late years in the care and treatment of the insane, this difference seems to be as wide as ever. It might be supposed, at first sight, that the establishment of hospitals for the insane would have furnished the requisite information, but the only effect these institutions have had thus far, has been to give us a keener sense of our ignorance of the matter. A new phase of the subject has been presented by Dr. Earle, Superintendent of the Hospital for the Insane at Northampton, in his recent Reports, and so confident is he of the correctness of his conclusions, and so many are the commendatory notices he has received, both at home and abroad, that they are entitled to a careful examination.

In his last as in his two next preceding reports, Dr. Earle has examined the matter of recoveries as exhibited in the statistics of our hospitals for the insane, and has been struck by some things so different from what might have been naturally expected, that he is led to seek for an explanation. He finds, as a general fact, that thirty or forty years ago the proportion of recoveries, or cures as they are sometimes called, was much larger than it has been of late years, and he proceeds to explain the fact in a way that is ingenious, if not satisfactory. It cannot be denied that to the observer of our own day the record is somewhat startling, for while it appears that once almost every patient recently attacked recovered, our statistics show that now, taking our hospitals together, hardly half of them have been so fortunate. This remarkable difference Dr. Earle attributes to two sources of error committed by those who reported the larger proportion of recoveries. One of them he describes as "the special characteristics of the person reporting them—his temperament, his constitutional organization, his psychological individuality." In another place he says, alluding to the medical officers of hospitals for the insane, "they are men 'with like passions as other men.' Self-interest, in some instances, and ambition in perhaps all—that ambition, at least, which is manifest in the desire to show as fair a record and as favorable results as are exhibited by colleagues in the specialty—have probably not been wholly inoperative in reporting recoveries from insanity, even though unconsciously to the persons producing those reports." I am not disposed to deny the correctness of the general principle here stated, but I do question whether it has had all the influence which is here attributed to it. Dr. Earle thinks it has sometimes led to a difference in the number of recoveries as reported, amounting to 25 per cent.

Again, Dr. Earle says that "the reported

recoveries from insanity are increased to an important extent by repeated recoveries from the periodical or recurrent form of the disease in the same person; and consequently the recoveries of persons are much less numerous than the recoveries of patients or cases; and consequently, from the number of reported recoveries of cases, or patients, it is generally impossible to ascertain the number of persons who recovered." After showing that these reasons are inadequate, Dr. Ray proceeded:—

As, then, neither the temperament of the physician, nor the repeated counting of periodical cases, accounts for the larger proportion of recoveries, in the earlier times, we must look for the explanation in another direction, and we shall find it in various agencies that have come into operation in later times.

Fifty years ago, when State hospitals for the insane began to be established, the main purpose for which they were to be used was that of receiving the insane inmates of the jails and almshouses, whose sad condition had arrested the public attention. It was not long before the benefit of hospital treatment became so obvious that it began to be sought for other classes of the insane, slowly increasing at first, with the slow growth of confidence. As might have been expected, the earliest of these was that of the violent and dangerous cases, that could not be restrained by any domestic arrangements consistent with comfort or decency. Even for the care of such it required a little more than an average intelligence and freedom from prejudice to see in the hospital one of the improvements of the age, destined to meet a fearful exigency in the human condition. It was not until a later period that patients of a different character—the quiet, the desponding the melancholic—resorted to the hospital. They had excited no fears, and conformed somewhat to the domestic requirements. There was no pressing necessity for their removal from home, and the superior fitness of the hospital for the care of such cases was seldom recognized. Now, we all know that in the form of disease first mentioned we have the largest proportion of recoveries.

And this result was promoted, unquestionably, by a circumstance too much overlooked in these discussions concerning the curability of insanity. Fifty years ago the country furnished a larger proportion of patients, as compared with the city, than it ever has since. Their general health was not appreciably impaired; they had spent their days working in the open air, and their natural forces had not been weakened by sensual indulgences. They were in the best possible condition to meet the inroad of mental disease. During this period a remarkable change has been going on in the distribution of our population. It is estimated on good authority that one-third of our population live in cities of 50,000 or more. Seventy-five years ago there was not one city of that size, and fifty years ago there were not more than ten. This great change in our social condition has been accompanied by a steady depreciation of the conservative powers of the constitution, strongly manifested in the physical condition of the patients admitted into our hospitals for the insane. The number attributed to ill health in the table of causes usually given in the annual report has been steadily increasing.

No array of figures, however, can convey such an impression of this remarkable difference as that derived from a personal observation embracing the whole period. Dr. Bell had good reason for saying, in his Report of the McLean Asylum, for 1840, "That the records of this asylum justify the declaration that all cases certainly recent—that is, whose origin does not, either directly or obscurely, run back more than a year—recover under a fair trial." In quoting this passage Dr. Earle admits, to use his own words, that "no abler man, intellectually, and no more conscientious man, morally, has been engaged in the speciality of psychology" in this country, and this being so, we are left in the dark how to explain this statement of Dr. Bell, which Dr. Earle must regard as gross exaggeration of the truth. It might be attributed, perhaps, to the influence of a sanguine temperament and the practice of curing the same person more than once, did not the sequel, as given by Dr. Earle himself, suggest a very different reason. It seems that in after years Dr. Bell reported a much smaller proportion of recoveries, the proportion pretty steadily diminishing during the latter fifteen years of his service. That is to say, as the community became more and more enlightened as to the beneficent purposes of the asylum, it was more and more resorted to by patients of the less violent kind, and by others affected by those incurable forms of the disease, whose care could be merely custodial. And this leads us to an incident in the history of insanity that must not be overlooked in our estimates of curability.

About forty years ago, when our country was rising from the financial depression that began in 1836, and the means of intercommunication had been greatly increased by railways and ocean steamers, a change began in the social habits of our people, as just intimated, manifested in a distaste for the quiet pursuits of a country life, in surrendering to the allurements of the city, and plunging into the struggle for the great prizes of life. The vitiated atmosphere of crowded streets and dwellings, the seductive appliances of ease and luxury, the mental strain required in the race of competition, the tumult of emotion under the frequent alternations of fortune, all these serve to lower the conservative forces of the system and invite the invasion of nervous disease. The tables of mortality tell the story in the figures assigned to apoplexy, paralysis, and cerebral congestions, and the records of our census show it in the steadily increasing amount of insanity in the last semi-centennial period. Not only did insanity become more frequent, but it also became less curable. And even new forms of disease appeared, and the wards of our hospitals were pervaded by a class of cases utterly unknown before. But little more than thirty years have elapsed since that remarkable affection, general paralysis, became known to American physicians, and there is no reason to suspect that it had been previously overlooked. Dr. Bell, who first observed it in Europe in 1845, satisfied him-

self, after a most thorough examination of the case books of the McLean Asylum, that up to that period no instance of it had been observed in that institution, though since then it has been frequent enough.

And we have now other cerebral affections which, once seldom seen in our hospitals, are no longer an extraordinary sight. I refer to those cases which seem to be closely affiliated to general paralysis, but do not present some of its characteristic symptoms. The same may be said of another affection, passing under the various names of Bell's disease, acute delirium, and typho-mania, which is eminently and speedily fatal. In these forms of cerebral disease the patient is insane, certainly, but the insanity is only an incident accompanying a deeper and graver affection, and they, of course, swell the death record, and to the same extent lessen the proportion of recoveries. Now, therefore, in considering the question in dispute, we shall leave out of the account a very important factor if we overlook this change in the pathological character of mental diseases.

Before leaving the subject I take the opportunity of saying that the experience of our hospitals, as given in their annual reports, is a fallacious test of the curability of insanity. Between this objective result and the facts on which it seems to be founded, there is really no necessary relation. If we had a right to believe that every patient discharged as *improved*, *unimproved*, or *stationary*, was incurable, then we might take the construction usually placed on the record. But we well know that such discharges indicate not the incurability of the disease, so much as the impatience, or perversity, or straitened means of the friends. Nothing can be further from the truth than the idea that they represent the results of a fair trial of hospital treatment. It is not at all unlikely that under such a trial of recent cases at least twelve or fifteen per cent. would be added to the number of recoveries. In order to approach a correct estimate of the curability of insanity, two requisites are still needed, viz., that every case should have a fair trial, and that the subsequent history of every case discharged should be ascertained. Without these, and we are not very likely to have them in our day, we can never have an estimate of the curability of insanity with any claim to scientific accuracy.

These, then, I believe, are the points which I have fairly made, viz.:—

1. Those qualities of temperament which lead men to unduly magnify their achievements are as common at one time as at another.

2. The practice of reporting cases instead of persons has not been confined to any particular period, and therefore, while it may vitiate our estimate of the curability of insanity, it cannot make the proportion of recoveries larger or smaller at one period than at another.

3. Cases marked by high excitement entered our hospitals in a larger proportion to those of an opposite character fifty years ago than they do now.

4. Under the influences of highly civilized life the conservative powers of the constitution have somewhat depreciated, and to that extent impaired the curability of insanity.

5. During the last fifty years cerebral affections in which insanity is only an incident have been steadily increasing, and thus diminishing the proportion of recoveries.

A paper was presented by Dr. R. P. Harris, describing a

Case of Congenital Ventral Gestation,

the subject being a girl, six years old, who recovered after the discharge of the fœtal mass from the abdomen, and lived seventeen years. It was reported on behalf of Dr. John L. Atlee, of Lancaster, Pennsylvania, with remarks on the condition in question.

The subject of the anomaly in question was Ann, daughter of Mr. Solomon Oswald, of York, Pennsylvania, aged six years, who presented in very early childhood an appearance of irregular conformation and enlargement of the abdomen. She was of delicate build, with fair complexion, light hair and eyes, and belonged to a consumptive family. In the progress of her disease an abscess formed in the lower portion of the epigastric and upper part of the umbilical regions, which opened, and a mass presented itself, which in time protruded through the abdominal wall. The physicians of York, fearing to explore this, applied ligatures on several successive occasions to the protruding portion, with the effect of removal by strangulation; under which process a very offensive effluvia was given out. Soon after these removals the whole remaining mass escaped, and this was preserved in a bottle of alcohol. It was then discovered that the inclosing sac still contained a mass of hairs, and as the patient was by this time in a very low state, she was carried upon a pillow to Dr. Atlee's, in Lancaster, for his professional advice, and the specimen in the bottle submitted to him for opinion. This was in the summer of 1844.

Dr. Atlee found a weak, delicate, emaciated girl, with an abdominal fistula, and hair protruding from it. He removed the hair, and having washed and dried it, found that it weighed two drachms. It was soft, light colored, and of varying lengths, the longest portions measuring from ten to twelve inches. After the cyst was emptied of its contents the girl's health began to improve, but it was soon discovered that the sac in some way communicated with the stomach, as evinced by the escape of articles of food through the fistula. Dr. Atlee writes: "Notwithstanding the care which was taken to allow nothing to be eaten but soft and easily digestible food, she had been so much indulged previously that she insisted on having berries, and green corn; and I well recollect, on one occasion, seeing a large quantity of whortleberries, and on another, of grains of Indian corn, which passed in that way."

When her general health had sufficiently improved the child was taken home, and attended to by her father, who was a very intelligent druggist. The cyst gradually contracted to a fistula, which continued open until she was fourteen or fifteen, when it closed up, leaving a button-like projection about the size of a quarter-dollar, which has always remained. The girl developed into a fine and handsome young lady, menstruated at the age of twelve, and continued to be

regular until she fell a victim to phthisis pulmonalis, at the age of twenty-three.

The mass contained in the bottle was sent to Philadelphia to be dissected and prepared by the late Prof. William R. Grant, by whom it is described as follows, in Atlee on Ovarian Tumors, page 199.

"The tumor, at first sight, appears to be an amorphous mass; . . . the upper and back portion, resembling in structure the scalp, is covered at present with a few scattered straight hairs. Its size is 3½ inches in length and 2 in greatest width; weight 2 ounces. Anterior to the scalp is an irregular horizontal fissure, supposed to be the rudiment of a mouth. Below this are three perfect temporary teeth, loosely attached to the soft parts or gums of the lower jaw. The exposed and prominent teeth are lateral incisor, bicuspid, and molar, superficially resting on alveoli of an imperfect jaw, within the body of which are imbedded one or two rudiments of other teeth, seen through an opening at the base. The maxilla has a ridge corresponding with the symphysis; it is movable on the left but anchylosed on the right side."

"Within the mass I have traced, with some difficulty, a skeleton, tolerably perfect, though considerably distorted. The cranium, which is large and hard, is united to a short but thick spine; the latter, inflexible, curved backward, and imperfect behind, constituting the malformation known as *spina bifida*, with ridges corresponding with the situation of intervertebral cartilages. At the open part of the spinal canal the cord is distinctly seen giving off filaments; one of these, which I take to be the sciatic nerve, was traced downward to the extremity of the foot. The bones of the head appear as if fused together; no traces of sutures. There are in it two openings, one in front near the centre, and the other corresponding with the situation of the posterior fontanelle. Each of these openings is about two lines in diameter; a small probe can be passed from one to the other, and from either downward, through the vertebral canal. The bones of the pelvis are well marked, though misshappen, joined at the pubes by a regular symphysis, covered with cartilage; in like manner to the spine. The acetabula are occupied by the cartilaginous heads of the femurs, round and prominent, with tolerably perfect capsules. The left knee and ankle joints are close together, and the foot turned inward (*varus*). The right side of the pelvis and right hip-joint correspond with the left; but a few lines below the whole extremity appears fibrinous, as if it had been exposed to the action of an acid, and had become partially dissolved. The rudiments of the upper extremities were also dissected from the mass, though not so perfectly as the lower, from their smaller size and less prominent position. I could discover no vestige of ribs, nor the appearance of any distinct organs or viscera. Covering the bones is a distinct periosteum."

It is very evident from this description of Prof. Grant, who was a skillful anatomist, that the body under inspection was not a dermoid tumor, but a product of generation, a twin, we may say, of the girl within whose abdomen the germinal trace was partially and irregularly developed. The monster by inclusion is certainly one of the most difficult of all the duplex types to comprehend and explain on the principles of teratological science. One germinal or twin trace would appear, for some unaccountable reason, to maintain a dormant vitality, like that of an unsprouted seed, or severed bud, while the other develops and surrounds it. In the changes of growth and nutrition that occur in the body after birth, the dormant germ appears to be better nourished, is stimulated to grow, and may finally assume the characteristics of a hard tumor, an abscess, or a cystic growth, especially if located in the abdomen, breaking down the health of the subject, and in almost all such instances ending fatally. In the case before us there is no mention of any ascitic or encysted fluid having been detected, and I presume there was no such complication to endanger the life. The probability is that the fœtal growth was much more superficially located than is usual in such caees, and hence the discharge of it during life, and the favorable termination of the case.

After a careful and extensive search for parallel reports, I find no authentic record in which a congenitally inclosed fœtus was removed from the abdomen during the life of the child with recovery. Dr. Harris added a condensed record of some of the most remarkable cases of fœtus by inclusion that have been published during the the last seventy-five years.

In regard to diagnosing such conditions, he said:—

The first important requisite in making such a diagnosis is to know the history of apparently parallel cases, and all the points of the one to be considered. It was in this way that M. Velpeau made his celebrated diagnosis in the case of scrotal tumor, at the Hôpital de la Charité, in 1840, before an audience of about five hundred students and physicians, stating that he expected to find in the scrotum of the man before them the rudiments of a fœtus, and verifying the correctness of his judgment, after removal and dissection. It appeared to be a very marvelous diagnostic feat at the time, and gave its author a world-wide reputation as a man of skill. No doubt some persons thought it a happy conjecture; but what were the facts?

In 1826 there appeared in the *Bulletin des Sciences Médicales*, of Paris, an account of an operation upon the scrotum of a child, by Mr. Fatti, of Braunau, Austria. The child was born with an enlarged scrotum, which increased in size as he grew, until it was five inches long by two and a half in thickness. Mr. Fatti laid it open, and discovered the ribs, vertebral column, two lower extremities as far as the knees, and the two orbits of a fœtus. Again, in 1829, the same journal presented a similar report, from Prof. Wendt, of Breslau, of an operation performed by him on a Silesian boy, seven years old. When the patient Gallochat came under the care of Prof. Velpeau, he was a man of twenty-seven years of age, and stated that he had had the tumor from the time of his earliest recollection. M. Velpeau, by correspondence with Dr. Senoble, of Esternay, learned that the latter had been consulted about an enlargement of Gallochat's scrotum when the patient was a

baby of four months old, and that the growth had enlarged as the boy grew up. There was also to be seen a tuft of hair protruding from a kind of ulcer at the posterior part of the tumor; and a reddish tubercle presented itself at the bottom of another opening anteriorly. The skin over the tumor was peculiar, and not like that of the scrotum proper; it was insensible to puncturing, but bled freely when cut; and besides all these points, the feel of the mass was indicative of the presence of bone. So, like the old story of Columbus and the egg, the matter is very simple when we know how it was done, but the merit lies in finding out how to do it. To know what has been found under similar circumstances and conditions, and to weigh and study with care all the points in the history of a case, will often make a diagnosis simple and unquestionable, where it might otherwise be impossible.

The historical evidences in intra-abdominal tumors are often of more value than palpation, percussion, bimanual pressure and the sound can possibly be without them. I have been forcibly reminded of this fact in two instances within the past year. In one woman the presence of an ovarian or uterine tumor had been diagnosed, where there was found to be a clear and connected history of a secondary abdominal pregnancy; and in the other, where palpation led to the suspicion that there was a fœtus in the abdominal cavity, there was no history indicative of pregnancy, but, on the contrary, good reason for regarding the abdominal growth as malignant. Such cases require time for a proper investigation, and the labor of obtaining a full history before any other method of examination is entered upon, is not lost. A rapid decision may savor of skill to the unlearned, but is apt to lead into error; it is, therefore, wiser sometimes to be slow. It will not be a very pleasing reflection, after having discovered an error of opinion, to find that the case had a history, the full investigation of which at first, instead of after the discovery, would have made the mistake an impossibility.

Although, as before stated, no one has as yet made a diagnosis recognizing the existence of a fœtal tumor in the abdomen of a young subject, and acted upon it by evacuating the contents of the same under the knife, we are not to regard such a procedure as a matter of impossibility in the future. Such an operation might prove successful; and in a case like that of Amidée Bissieu, a correct diagnosis would not be very difficult. In one of the character of that treated by Dr. Atlee, we can see that an early evacuation by the knife might have been quite feasible. The nearest approach to the removal of a fœtal tumor from the abdomen is that of the excision of dermoid cysts of the ovary in young children, the youngest case on record being perhaps that reported through Dr. J. Ewing Mears, operated upon at the age of six years and a half, by T. S. Bradford, of Augusta, Kentucky, at Higginsport, Ohio, in 1871. The little girl recovered in eighteen days. In the cyst were found three pints of fluid, with a collection of hair, fatty matter, and an irregularly-shaped osseous mass.*

These dermoid cysts have long been a puzzle to the physiologist, and their origin is still in large measure hypothetical. At one time the finding of such a formation in the ovary of an unmarried woman was regarded as presumptive evidence that her life had at some time been unchaste; but the discovery of the same character of growths in very young children, and their being even detected in the fœtus at and before term, have dissipated this idea, and substituted for it the belief that the true dermoid cyst is always fœtal in origin, and never appears late in life except as the development of a formation originating in utero, and remaining dormant for a term of years. As the development of a fœtus within the parenchyma of an ovary is of such rare occurrence that the possibility of it has been repeatedly denied, it is not probable that a dermoid cyst of the same organ would originate by direct impregnation in a nubile subject.

It is the death of the included fœtus that endangers the life of the subject. In a few instances on record the interior parasite was found in the bodies of adult male subjects, one as old as fifty, who had died of some independent malady, the fœtus being free from any trace of morbid or cadaveric change. just as we see to be the case in some instances where extra-uterine fœtuses have been carried for years. When the fœtus becomes, by its death, a foreign body, nature rebels against its presence, and inflammation, followed by an abscess or dropsical effusion, is set up. In some rare cases the bones and tissues have broken down and been discharged, and a spontaneous cure effected; but much more commonly the patient dies, as in the examples given.

Periscope.

Displaced Retina Treated by the Wire Seton.

In the *Medical Times and Gazette*, Mr. Chas. Higgens gives a number of cases of this method of treatment, with remarks. We quote one case and his observations—

Case 1.—James F., aged thirty-seven, admitted December 5th, 1877. Left eye: Considerable displacement of retina at lower part; vitreous cloudy; some floating opacities besides the displaced retina; optic disk visible, apparently healthy; central corneal opacity. Right eye: Some dimness of vision; eye is hypermetropic, 2 D.V.=$\frac{6}{6}$. Seton of fine gold wire passed

through sclerotic and choroid, between the latter and the displaced portion of retina; the points of entrance and exit of the wire were situated between the external and inferior recti muscles, close to their insertion.

January 8th, 1878: The seton caused no irritation; it could be plainly seen with the ophthalmoscope behind the displaced portion of retina. No improvement had taken place. The wire was removed; iridectomy performed downward. 29th: Conjunctiva divided with scissors and turned back. A small piece of sclerotic removed with trephine, immediately behind the ciliary region, and at a point midway between the insertions of the external and inferior recti muscles; the choroid, which bulged into the opening made by the trephine, punctured with a Graefe's knife. A gush of clear fluid took place. Wound in conjunctiva closed with suture; no irritation followed. The wound in sclerotic gradually contracted. On December 9th, 1878, the retinal displacement remained the same; the opening made by the trephine appeared as a bluish, nearly circular spot. The eye could count fingers in the lower and outer part of the field, the remainder of which was entirely wanting.

Knowing the disastrous results which frequently follow the accidental lodgment of foreign bodies within the eye, I was quite prepared for what might follow the intentional introduction of a piece of wire; on the other hand, I knew that pieces of metal had often lodged in the vitreous and remained there without causing any irritation. In Cases 1 and 3 the wire remained in the eyeball for one month, and nearly two months, respectively—in the former causing no irritation, in the latter but little. In Case 2, however, what I feared occurred: within three days of the operation, a violent irido-choroiditis was set up, which entirely destroyed the eye, rendering necessary its excision at a later period. Removal of a portion of the sclerotic appeared to be a much safer operation than the introduction of a seton, and in the three cases reported no bad symptom followed. Both operations are extremely simple. For the introduction of the wire seton I used a curved hollow needle; a piece of gold wire about as thick as a human hair was pushed into the tube of the needle, just far enough to prevent it slipping out; the needle was then passed through the tunics of the eyeball into its interior, brought out again at the distance of about one or two centimeters from the point of entrance, and detached from the wire, the two ends of which were tied in a knot, and cut off short. The portion of sclerotic is removed by a small trephine having a screw fixer in its interior, upon which it works by means of a left-handed screw; it is an aural instrument, and was given to me by Mr. L. Purves. When the instrument is used, the conjunctiva is first divided and turned back; the screw fixer, protruded beyond the end of the trephine, is then screwed firmly into the sclerotic, and slight traction exerted; the trephine is then rotated from right to left, and passes down over the head of the fixer, by which the sclerotic is drawn into its mouth, and cut by being pressed against the trephine. As soon as the sclerotic has been perforated, the instrument comes away from the globe, the choroid bulges into the little circular opening and is punctured with a knife. Some clear fluid, perhaps followed by a small quantity of vitreous, escapes. I did not expect much from the operative treatment of displaced retina, but hoped that, at any rate, my patients would be made no worse; in this even—so far as the introduction of a seton goes—I was disappointed. The trephine did no harm, but, on the other hand, did no good. I have used it with beneficial results in some cases of absolute glaucoma, where the globe was painful. Possibly further trial may give more encouraging results in displacements of the retina.

Cases of Syphilis.

The following interesting cases are reported in the *Lancet*, by Dr. Jonathan Hutchinson:—

A young man was admitted six weeks ago, with a large indurated sore on his lip. Its characters were most definite, and under the jaw were a number of enlarged glands. The skin was covered with a lichenoid and papular rash. He did not know how he had caught the sore. He first observed a little crack, then a month later it began to inflame and harden, and in another month the rash began to appear. Having remarked on the case as an example of non-venereal syphilis (*syphilis sine coitu*), or probably chancre from kissing, I drew attention to it as an illustration of the early stages of the disease. For practical purposes we may divide the early phenomena of syphilis into three periods of one month each. The first month is occupied by the incubation of the chancre, and during it there is either no sore at all, or a sore which is soft, suppurating, and without definite character. At the end of this first month the process of induration will be commenced. Another month may be allowed for the full development of the chancre and for first appearance of the constitutional symptoms; and at the end of two months from the contagion the sore may be expected to be very hard, the bubo well characterized, and the skin mottled with a roseolous rash. If treatment be avoided, the rash will develop further during another month, and at the end of three the chancre will still be in full vigor and the skin covered with a multiform eruption. The disease will now be at its full height, and it is at this period that iritis and retinitis are most likely to occur. In this case the lad has now been one month under treatment by two-grain doses of gray powder three times a day; and, without ptyalism and without any interference with general health, the induration has melted away, and the rash almost wholly disappeared.

In connection with the above, in which syphilis is being cured by small doses of mercury administered through a long period, salivation being avoided, I drew attention to another, which occurred a month ago, in which profuse salivation appeared to be productive of the best results. A married woman of middle age was admitted with a most copious scaly and papular eruption. It covered her face, trunk, and extremities, not any part escaping, and the profuse production of scale crusts was a very remarkable feature. On

the arms it might have been mistaken for common psoriasis, but on the face there could be no doubt as to the diagnosis. Mercurial baths were ordered, but after the third she became freely salivated. For a week or two she was confined to bed, and in a very feeble state, from the profuse ptyalism. During this period the eruption vanished as if by magic. No more mercury was used in any form, and at the end of a month the woman left the hospital covered with stains, but having nothing whatever remaining but stains. She was charged to return in a month, that we might know if any relapse occurred.

I remarked in connection with this case that it was the most rapid cure of a severe secondary eruption which I had ever known. Although, on the whole, I prefer the long continued treatment by small doses, yet it is well to bear in mind that in certain cases mercury appears to be far more efficient when pushed to its full physiological influence. We must avoid prejudging the question, and keep our minds open for the reception of all evidence that may be forthcoming. In some acute inflammatory affections, not syphilitic, benefit is observed immediately that salivation occurs, while none is witnessed before.

Poisoning from Arsenical Wall Paper.

At a meeting of the Medical Society of London, Mr. Jabez Hogg drew attention to two points in connection with this subject; (1) as to whether the symptoms produced by the dust thrown off from the walls differs from those observed in the administration of arsenic as a medicine; and (2) whether the greater amount of activity and virulence observed in wall-paper poisoning is due to the poison being taken as a finely divided dust, or as an evolved gas. The symptoms of arsenical conjunctivitis seemed to indicate a special form of disease produced by the mechanical irritation of the dust, leading to purulent discharge and ulceration of the mucous membrane; varying degrees of symptomatic fever attend the attack, the digestion is deranged, appetite impaired, bowels irritable, tongue white, furred and sore; the mouth dry and throat sore. He dwelt especially on the local manifestations, and then proceeded to quote several well marked instances that had come under his notice; reading an interesting account by Professor Osborne Reynolds, of Manchester, of the symptoms in his own case. The effects upon workmen engaged in the various manufacture of papers, calicoes, etc., were then shown; and a description given of the various kinds of arsenical pigments employed, which, as they become dry, are easily detached, and float about in the air of the room. It was important to know whether the ill effects produced were due to dust or to arseniuretted hydrogen. Three important points had been arrived at: (1) that dust is separated in sufficient quantities to give rise to a peculiar train of symptoms; (2) that under certain conditions arseniuretted hydrogen is evolved by decomposition, and may naturally add to the virulence of the poison; (3) that at all events the dangers to the public health from the use of arsenical pigments are real and urgent. Wall paper could be made without arsenic; and he considered that the evils connected with a nefarious manufacture of those made with poisonous compounds called for the entire prohibition of the sale of the same.

On Villous Disease of the Bladder.

An article on this rare disease is contributed to the Dublin *Medical Journal*, by Dr. R. S. Hudson. His conclusions are—

1. Villous disease of the bladder is not so rare as is generally supposed, many so-called cases of chronic cystitis being probably due to it.
2. Its diagnosis is most difficult, and can only be arrived at after long observation, and by a process of exclusion.
3. Urinary deposits containing so-called cancer cells are very misleading; but the microscope is most valuable in detecting small portions of genuine villous growth.
4. There should be no difficulty in detecting the growths in the female, as the whole internal surface of the female bladder can be readily explored with the finger after rapid dilatation of the urethra, when under the influence of an anæsthetic.
5. Astringent injections are likely to be of use in the early stages, and before the growths have become pedunculated.
6. The surgeon, while unsparing in the use of sedatives to relieve pain and spasm, should bear in mind the possibility of permanent cure by removal of the growth.
7. Statistics show that the operation is neither difficult nor dangerous in the female; and there are good grounds for believing that when preceded by cystotomy in the adult male it will prove justifiable and satisfactory.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——The third annual report of the State Board of Health of Wisconsin makes a volume of 183 pages, with much interesting matter, as will be seen from the contents, which are as follows:—"Diphtheria and its Relations to Filth," by Dr. E. L. Griffin; "Typhoid Fever and its Prevention," by Dr. Solon Marks; "Land Drainage," by Dr. J. T. Reeve; "Preventable Causes of Insanity," by Dr. W. Kempster; "Influence of Reading upon Health," by Prof. R. B. Anderson; "Water Supply of Wisconsin," by Dr. G. F. Witter; "Reports on Water Supply," and "Investigations of Water Supply of a City," by Prof. Chittenden; "School Buildings," by the same author; "Inspection of Public Buildings," and "Extracts from Special Correspondence." During the year the Board has distributed among the public a number of copies of a tract containing suggestions for the restriction and prevention of diphtheria.

——The proceedings at the complimentary dinner given to Prof. S. D. Gross by his medical friends, in commemoration of his fifty-first year in the profession, have been published in neat form, on handsome paper, with a fine photograph of the distinguished surgeon. It will make a pleasant memento for his many friends. Published by Lindsay & Blakiston. pp. 42. Cloth. Price $1.00.

——A hitherto undescribed form of skin disease is reported by Dr. Arthur Van Harlingen, in a reprint from the *Archives of Dermatology*, under the name of "Ulcerative Scrofuloderm." It is analogous to the affection described by Bizzero and others as "tuberculosis of the skin."

——The National Board of Health has commenced a weekly Bulletin, to contain general information, official and otherwise, on the public health. It is also intended to publish in the *Bulletin*, from time to time, such local quarantine and other sanitary regulations as may be adopted by the various State and municipal authorities throughout the United States, and it is hoped that boards of health, quarantine officers, and others, will keep the Board fully advised of all such rules and regulations, and of any changes that may subsequently occur in them.

——*Lippincott's Magazine* for August is a capital summer number. It opens with a paper, the first of two, on "Catskill and the Catskill Region," which will be likely to swell the stream of travel in the direction of that beautiful mountain country, the article evincing a perfect knowledge and keen appreciation of its peculiar beauties, while the illustrations are of first-class excellence. Dr. Oswald continues his admirable "Summerland Sketches," which are also finely illustrated. A paper entitled "Guignol" describes the marionettes of the Champs Elysées, and other public gardens of Paris, with curious details and engravings. There are also many other articles of interest.

BOOK NOTICES.

On Diseases of the Stomach, the Varieties of Dyspepsia, their Diagnosis and Treatment. By J. O. Habershon, M.D., London. Third edition. Philadelphia, Lindsay & Blakiston. Cloth, 8vo, pp. 324. Price $1.75.

For many years Dr. Habershon has enjoyed a high reputation in London, largely for the successful attention he has given to diseases of the abdomen and its contents. Most of the present volume is occupied with the numerous forms of dyspepsia; chapters are also given to ulceration, degeneration, cancer, and spasm of the stomach; and to a discussion of the relations of diseases of the stomach to those of other organs and to the general health. Dyspepsia is divided into many varieties; atonic, congestive, inflammatory, hepatic, rheumatic, gouty, renal, mechanical, sympathetic, fermentative and duodenal. To each of these a separate chapter is assigned.

We have been pleasantly impressed by the daring of the author in the following sentence in his preface: "There are some truths which are continually impressed upon the mind of the physician, and perhaps none more forcibly than the importance of endeavoring to *cure the patient*, rather than of merely seeking to *treat the disease*." In these days of therapeutic skepticism, all talk of *curing* is looked upon by certain high-science writers as unbecoming. It is refreshing to find there are solid physicians yet who recognize *curing* as the special and most proper field of the Profession.

Laboratory Teaching; or Progressive Exercises in Practical Chemistry. By Charles Loudon Bloxham, Professor of Chemistry in King's College, London, etc. Fourth edition. With eighty-nine illustrations. Philadelphia, Lindsay & Blakiston, 1879. Cloth, 8vo, pp. 261. Price $1.75.

The practical value of Bloxham's manual is fully shown by the demand for a fourth edition. The alterations are not important, the most prominent being the introduction of the formulæ representing the various chemical compounds described in the notes to the tables. The instructions for manipulations are clear, the tables will be of much convenience, and the illustrations are ample and well printed.

Memoranda on Poisons. By Thomas Hawkes Tanner, M.D., F.L.S. Fourth American, from the last London enlarged and revised, edition. Philadelphia, Lindsay & Blakiston. 18mo, cloth, pp. 207. Price 75 cents.

Since Dr. Tanner's death this little book has passed through two editions, under competent editorship, and as a ready guide in toxical accidents it will often be of service to the practitioner. Considerable additions have been made to the original form of the book. The remarks under General Toxicology, on the diagnosis of poisoning and the detection of poisons, merit careful reading by all.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

NERVOUS DISEASE AS A CORRELATIVE OF CIVILIZATION.

There has been of late years a good deal of talk about the increase of insanity and functional nervous disease, which has been supposed to be discoverable in modern times. Quite lately a well known American neurologist, Dr. GEORGE M. BEARD, a writer widely and favorably esteemed for his works on medical electricity, has been making some assertions on the subject remarkable for their positiveness, and we must add for their utter want of foundation in fact.

We take one of the latest essays of his fertile pen, a pamphlet entitled "American Nervousness, its Philosophy and Treatment," reprinted from the July number of the Virginia *Medical Monthly*. The theory the author advocates at great length is that an increase of nervous diseases has been the direct result of civilization, and that they are comparatively rare among uncivilized and savage races. We quote his own words, so as to be sure to give his position its correct meaning. He says (p. 6)—

"In the study of this subject, I have compared a very large number of books of travel, and I have arrived at this fact, in regard to which there can be no doubt whatever, namely, that nervous disease scarcely exists among savages or barbarians, or semi-barbarians, or partially civilized people."

Now, what we have to say of this is that no statement on the subject could be framed more glaringly incorrect and more distinctly contrary to known and undeniable facts than the one presented in this extract. We maintain that just the reverse is true; that nervous disease is vastly more prevalent among uncivilized conditions than in those which are civilized; and how Dr. BEARD, well read as he is, could have been led to make such a statement can only be explained by the determination, so common among men of science, to force all facts to support their chosen theories.

We have but to turn to any history of medicine to prove his error. Take the first at hand. No one will question the weight of historic authority which goes with Hæser's *Geschichte der Medicin*. We turn to p. 282 and read: "Among the most remarkable phenomena of the pathological life of nations belong those which display themselves not in disturbances of the vegetative sphere of life, but through the various and singular outbreaks of a morbidly irritable nervous activity. It is certainly not without profound significance for the history of the physical development of man that the almost epidemic prevalence of nervous disease occurred most frequently in early antiquity and in the middle ages, as this class of diseases is also principally found to-day among persons of the uncultivated classes and among various savage peoples; while they are incomparably less frequent (*ungleich seltener auftreten*) in periods of higher civilization, and where there is greater harmony between the psychic and somatic spheres of nerve life."

After this most striking and direct refutation of Dr. BEARD'S view, by one of the most profound historians of this century, we need not add in detail the proofs which Hæser marshals

in invincible array. We need but mention the lykanthropy, the St. Vitus dance, the childrens' crusade, the witch mania, the gross illusions, the contagious superstitions, the flagellants, and the epidemic manias which in a hundred forms scourged the Christian world in the dark ages, and which far surpass any nervous outbreak this age has seen.

As for the statement that "nervous diseases scarcely exist among savages or barbarians," Dr. BEARD must have read the large numbers of books of travel he refers to with extraordinarily little attention not to have learned that precisely this class of diseases is frequent and violent among them, beyond anything civilization can parallel. If any one will convince himself of this, let him, for the Lapps, Samoyeds, Ostiaks and Kamschatkans, consult Schnurrer, *Geographische Nosologie*, page 234, or the eminent Professor CASTREN'S recent travels among the same races. Would he learn of their prevalence among the native races of North and South America, let him read the tenth chapter of BRINTON'S *Myths of the New World*. Would he find them among the half savage tribes of India, let him peruse almost any work which describes in true colors the scenes on the pilgrimages, at the festivals, and in the temples of those peoples, when their nervous system is subjected to the strain of superstitious joy and fear. We might add references by the dozen, but it is really needless, as any one not blinded by theory can find them in abundance.

This talk of increasing nerve disease with increasing civilization is utterly at variance with the facts of history, and it is time that it ceased. Dr. BEARD has been by no means the only one who has been led to adopt it; but he is one of the latest and most dogmatic in his assertions. We have a very high respect for his industry and abilities; but in this, as in some former theories which we criticized a few years ago, and which we are glad to see he has dropped, we cannot refrain from showing that he is entirely at issue with the facts of the case, and with the unanimous voice of historians and unprejudiced observers.

SANITARY REGULATION OF SAILORS AND BOATMEN.

The extension of epidemic and contagious diseases through commerce and emigration has long been a subject of serious consideration for students of State medicine. Restrictions which harass the mercantile community, or which interfere with the free movements of population, are inconsistent with an enlightened popular government, and are imposed with hesitation, even by the decaying monarchies of the Old World. The golden principle of legislation laid down by the philosopher Comte, to the effect that the majority should be educated up to the point of desiring a law before it is formally enacted, here comes into play, and hence, in all sanitary legislation, the first duty of the enlightened reformer is to *educate the masses*, to show them that the measures needed to preserve the general health are also profitable to the individual, and if possible prove this by a practical exhibition of the good effects of a proposed enactment before it is formally incorporated among the statutes.

An instance where this is being carried into effect is in the excellent measure proposed by Dr. HAMILTON, Superintendent of the Marine Hospital Service, in providing for the examination of seamen about embarking in the mercantile marine. This examination is furnished by officers of the Marine Hospital Service, without charge, at the principal ports of the United States, and we learn is beginning to be highly appreciated by ship owners and captains. They find that the usefulness of their crews is much enhanced, and that, therefore, the safety of craft and cargo, and the net result of the venture, are all benefited by having really able-bodied seamen, rather than by shipping diseased and broken-down men, who become a burden and an expense to the crew, the officers and the owners. Both in Philadelphia and New York the number of seamen examined has been large, and is constantly increasing, and the wisdom of such an arrangement is daily becoming most apparent to those most deeply interested.

The extension of such an inspection to emigrants were desirable, and in certain conditions,

to all travelers. In time, no doubt, this will be acknowledged by all civilized nations, and hence a danger connected with our modern increased intercourse will be avoided. Many of the difficulties surrounding the question of quarantine would thus be avoided. The suggestions of Dr. MARION SIMS, in his presidential address before the American Medical Association, will be remembered in this connection. He thought that by carrying out such a plan carefully and systematically, even venereal diseases could be greatly diminished and reduced to insignificant proportions. No doubt they are carried from port to port by mercantile vessels, and that an exclusion of sailors suffering from them would be a salutary provision.

The work of the Marine Hospital Service in this respect is not confined to foreign commerce. The Service has given much attention, and has published several able reports on the extension of disease by river steamboats, and the measures best calculated to prevent such extension. These come naturally within its domain and will continue to receive its careful supervision.

The condition of the canal boatmen in England has of late attracted much attention from medical authorities. They live with their families in these floating houses, move from place to place, and often sadly neglect the first principles of sanitation. They escape the vaccination act through their migratory existence, and hence disseminate smallpox; while their morality has been slight, and the consequences of its absence apparent.

We do not remember to have seen any sanitary investigation by the officers of the Service, in reference to the numerous canal boatmen of this country; and would suggest the propriety of an examination into their condition, presuming that they also would come under the classification of the mercantile marine service. Probably similar deficiencies of sanitation exist among them here as in England.

—A satire on the mania for attaching undue importance to trifling variations in instruments is contained in a reprint from the Louisville *Medical News*, entitled, "An Account of the Perineosinuexereeinator."

NOTES AND COMMENTS.

Therapeutical Notes.

SKIN DISEASES.

We extract the following formulæ from Mr. Squire's "Pharmacopœia of the British Hospital for Diseases of the Skin" (just published in London), as exhibiting the use of some new remedies and approved combinations.

CHRONIC URTICARIA.

As a sedative, the following acid bath—

℞. Acidi nitrici, ℥ iss
Acidi hydrochlorici, ℥ j
Aquæ, Cxxx. M.

The patient should be immersed for not less than an hour, and the bath maintained at an even temperature of 90° Fahr.

The following cutaneous sedative is also recommended—

℞. Aquæ chloroformi, ℥ ss
Aquam, ad ℥ j.

Mix and apply locally.

Another useful sedative in the same disease is a saturated solution of benzoic acid in water—

℞. Acidi benzoici, gr. ij
Aquæ. ℥ j.

Dissolve.

CHRONIC ECZEMA.

A carbolic acid lotion, gr. x, to water, ℥ j, is used to allay irritation. As a mild stimulant, a pigment of aloes—

℞. Aloes extracti barbad., ℥ iij
Glycerini, ℥ vj.

Dissolve.

An ointment of birch oil is used cautiously in dry eczema—

℞. Olei betulæ albæ, ℥ ij
Ceræ flavæ, ℥ ij. Melt.

In subacute and chronic forms, the oleate of zinc is soothing—

℞. Zinci oleatis, ℥ ij
Adipis, ℥ j. M.

CHLOASMA, LENTIGO.

For these troublesome discolorations of the skin an ointment of alizarin is recommended:—

℞. Alizarini factitii, ℥ j
Adipis, ℥ j. M.

Or a sulphurous acid lotion:—

℞. Acidi sulphurosi, ℥ ij
Aquam, ad ℥ j.

The rapid evaporation of the acid from the lotion should be retarded by applying the lotion on lint or rag covered with oil silk.

As a bleaching agent in lentigo:—

℞. Sodæ chloratæ liquoris, ℥ ss
Aquæ, ℥ j. M.

Chrysophanic acid ointment is also useful in these affections.

PSORIASIS.

Chrysophanic acid is a leading remedy:—

℞. Acidi chrysophanici, ʒ ij
Adipis, ℥ j.

Heat together in a water bath for half an hour; when set, mix with pestle and mortar.

The erythema which arises after sometimes only a few applications of this ointment should be watched for, and on its first appearance the use of the ointment should be promptly discontinued. It should never be applied in the vicinity of the eyelids, as they are apt to be rendered œdematous.

Pyrogallic acid ointment is also used—

℞. Acidi pyrogallici, gr. x
Adipis, ℥ j. M.

As a solvent and stimulant a lotion of sulphurate of potash:—

℞. Potassæ sulphuratæ, gr. v
Aquæ, ℥ j.

Dissolve.

A New Method for Cupping Extempore.

The following practical advice is taken from an Italian journal, by the London *Medical Record*: Take a piece of common paper, of the size of the opening of the cupping glass, and dip it into warm water before applying it. The paper being damp, the skin is kept cool, and prevents, by the evaporation of the water, the too extensive spreading of the vacuum. If the same piece of paper be used twice, it must be dipped in water before the second application. As far as the cupping-glasses are concerned, a large number of household articles which can be had everywhere, such as tumblers, jam-pots, etc., may take their place, if the paper be applied to them in the way we have described. Half a dozen similar recipients, which are from three to five inches deep and wide, if applied at once, and the vacuum renewed every two or three minutes, will, in about a quarter of an hour, produce a most prodigious effect.

Impure Eucalyptus Oil.

One reason why so many failures with *Eucalyptus Globulus* are reported may be owing to the frequent substitution for it of other species of Eucalyptus. Our pharmaceutical exchanges assert that genuine volatile oil of eucalyptus globulus hardly ever appears in the market, the oil being almost invariably distilled in Australia, from the leaves of E. amygdalina, which contains more oil than any other known species of eucalyptus. E. globulus, of which 100 pounds of leaves yield about 6 ounces of oil, grows in not easily approachable districts. The two oils resemble each other very much; that of E. globulus possesses, however, much more therapeutical efficacy.

Results of Consanguineous Marriages.

A physician of Massachusetts has been collecting statistics of consanguineous marriages. He states, in the Boston *Medical and Surgical Journal*, that he received accounts of twenty-five such marriages, resulting in the birth of one hundred and seven children. Of these, ninety-two were sane, four insane, and eleven idiotic. Of the fifteen whose minds were unsound, nine became so from known causes other than the consanguinity of parents. Only six, then, of the one hundred and seven children could have been made insane by the near relationship of their parents, and even in these cases there may have been other causes. He thinks the danger of such marriages has been exaggerated.

The Solid India-rubber Bandage.

Dr. A. F. McGill, Surgeon to the Leeds Dispensary, writes to the *Practitioner*:—Since the commencement of the present year I have used, with excellent results, the solid rubber bandages introduced by Dr. Martin, of Boston. The bandage has been put on next the skin, without any other dressing; the patient has been instructed (1) to remove the bandage on going to bed, (2) to wash the leg with warm soap and water, (3) to sponge the ulcer with carbolic acid lotion and keep this applied all night, (4) to have the bandage well washed and hung up unfolded during the night, (5) to again wash the leg in the morning, and (6) to apply the bandage before leaving bed.

Cantharidin from the Potato Bug.

It appears from some experiments detailed in the American *Journal of Pharmacy* for June, that the fresh powder of the potato bug yields about 1⅛ per cent. of pure cantharidin. This is a large product, and no doubt these pests will be increasingly used as a cheap source of this valuable remedy.

A Sign of Mental Unsoundness.

We have often had occasion to note the correctness of the following remark, which we take from a writer in the last number of the *Journal of Mental Science*:—

"It is a fact, we believe, that the religionists of whose creed faith without works, sudden 'conversions,' and immediate, almost super-

natural answers to prayer form an unreasonable part, are greatly given to homœopathy and other systems of therapeutics where the means are not adequate to the end, according to ordinary known laws."

Use of Croton-chloral.

At a late meeting of the Boston Society for Medical Observation, Dr. H. I. Bowditch reported a case of facial neuralgia which had been relieved in a decided manner and without any unpleasant effect, by three five-grain doses of croton-chloral, after all other drugs had failed to give relief. Dr. Williams stated that he had often used it with advantage instead of opium, after operations about the eye. The chloral had no unpleasant effect, and he thought it safer. Dr. J. O. Green remarked that he had used this drug at the City Hospital, in cases of neuralgia of the head, and had obtained a wonderful effect in one case.

Correspondence.

LETTER FROM CINCINNATI.

Combined External and Internal Version.

Ed. Med. and Surg. Reporter:—

Who has not appreciated the advantages of second-hand book stores? Surely your correspondent has reason to "bless the man who first invented" them. An idle half-hour recently tempted me into a well-known establishment on Race street, where all sorts of works are offered for prices much more satisfactory to one's pocket than those prevailing in more aristocratic-looking places. A huge pile of unbound pamphlets attracted my eyes. They were nothing less than the "Transactions of the Ninth Annual Meeting of the Ohio State Medical Society, held in Cincinnati, June 6th, 1854." On page 59 of this volume is found this announcement: "Prize Essay; by M. B. Wright, M.D., of Cincinnati; *Difficult Labors and Their Treatment.*" Forty pages are devoted to Dr. Wright's communication, and twelve illustrations convey to the eye the ideas that words alone would fail to render clear. Now, to those who, like the writer, have received their professional training since 1860, there is no more striking landmark in modern medical literature than that reared by Braxton Hicks in the pages of the *Lancet*, some time in 1860. Yes, furthermore, there is no fact the value of which is susceptible of such complete demonstration. The writer well remembers the enthusiastic clinical teacher who exhibited to two hundred students the practicability of Hicks' combined external and internal version, by bringing before the class a woman in whose case labor had just commenced, and then, with the fingers of one hand at the uterine neck, and the palm of the other hand flat on the woman's abdomen, the position of the child was reversed by such digital manipulation as he was able to apply at the points mentioned. Originally a hand presentation, with the occiput to the left acetabulum of the mother, under the manipulations of the teacher, conducted as Hicks directs, the head of the child was made to ascend and the pelvic extremity to descend, until a breech presentation was produced. The same simple digital movements were continued, and in another moment a presentation similar to that at first was effected. Reversing the direction, the head of the child was passed from behind the left acetabulum of the mother to the right side of her pelvis, thence to the uterine fundus, and thence "to the place of beginning." The rapidity with which this change of position was effected, and the ease with which the manipulations were wrought, made a profound impression on the writer. Not so very long afterward, when called to the bedside of a patient whose young attendant lacked experience as well as years, there was a repetition of this clinical demonstration, in which the absence of the two hundred students was the only feature lacking to make the one case a *fac simile* of the other. In truth, I have never missed an opportunity of familiarizing any inexperienced practitioner with what I regard as the most important obstetrical improvement of recent years. Feeling thus strongly on this point, you can imagine my surprise and pleasure at finding what accident had thrown in my way. To show how valuable a treasure it was, let me quote a few words from page 82 of the "Transactions," where Dr. Wright says:—

"Suppose the patient to have been placed upon her back, across the bed, and with her hips near its edge, the presentation to be the right shoulder, with the head in the left iliac fossa, the right hand to have been into the vagina, and the arm, if prolapsed, having been placed as near as may be in its original position across the breast. We now apply our fingers upon the top of a shoulder, and our thumb in the opposite axilla, or on such part as will give us command of the chest, and enable us to apply a degree of lateral force. Our left hand is also applied to the abdomen of the patient, over the breech of the fœtus. Lateral pressure is made upon the shoulders in such a way as to give to the body of the fœtus a curvilinear movement. At the same time the left hand, applied as above, makes pressure so as to dislodge the breech, as it were, and move it toward the centre of the uterine cavity. The body is thus made to assume its original bent position, the points of contact with the uterus are loosened and perhaps diminished, and the force of adhesion is in good degree overcome. Without any direct action upon the head it gradually approaches the superior strait, falls into the opening, and will, in all probability, adjust itself as a favorable vertex presentation. If not, the hand may be acted upon as in deviated positions of the vertex, or it may be grasped, brought into the strait, and placed in correspondence with one of the oblique diameters."

Can anything be simpler? Both hands are to be used, one within the vagina, the other on the patient's abdomen, and version is to be performed. If this is not version by combined external and internal manipulation, words have

lost their meaning. Granting that words do mean what they are generally used to express, and that Dr. Wright did mean what he said, and what he says he meant when he used the above-quoted language, let us glance at the significance of his instructions.

Cephalic version dates from Hippocrates, and up to the adoption of podalic version, in the middle of the Sixteenth century, turning by the head was regarded as the safest and best method of terminating a preternatural labor. Although superseded by podalic version at the time mentioned, it was not abandoned, for Guillemeau continued to practice cephalic version in the early part of the Seventeenth century, even after recommending version by the feet. Two methods of performing version by the head have been popular. In one the head is brought to the pelvic opening by the hand of the operator inserted through the vagina; in the other the shoulder is gently pushed aside and the descent of the head is solicited. These methods were denominated cephalic version by internal manipulation. The possibility of version by external manipulation was referred to by Dr. John Peachy, in 1698. He says we may often succeed in bringing the head to the superior strait by acting on the uterus through the abdominal walls, and assisting the descent by the posture of the woman. Velpeau rediscovered this fact; Martin, of Jena, gives details of thirty-four cases in which this process was adopted; while Mattei, of Paris, in an essay in 1855, advocated the practice and predicted its universal adoption. In June, 1860, Fordyce Barker, of New York, reported a case, successful to mother and child, in which external manipulation had effected cephalic version. Srtange to say, when both external manipulation and internal manipulation were separately known to be efficacious in effecting cephalic versions, how happens it no one proposed combining them? This is the point to which I desire to call your attention; the miserable little pamphlet I purchased for five cents contained the first printed reference to rectifying abnormal positions by combined external and internal manipulation. If we perpetuate the name of Flammaud in connection with version by internal manipulation, and Wigand with that by external manipulation, so much the more should we indelibly connect the name of Wright with the plan he introduced, which is so much the superior of either or both the foregoing—the method of bimanual version by combined external and internal manipulation!

But what discovery has not its contestants? Dr. Braxton Hicks disputed Dr. Wright's claim to originality. Leishman says that while Gooch, Hamilton, etc., effected cephalic version by manipulations purely internal, and Wigand and Martin by a method exclusively external, it is to Braxton Hicks that we owe the combined method. If such is the case, all the more honor to Braxton Hicks, say we. Playfair claims that to Hicks "belongs the merit of having been the first to show the possibility of effecting complete version by combined external and internal manipulation. of laying down definite rules for its practice, and thus popularizing one of the greatest improvements in modern midwifery." Hicks himself, in a letter to the *American Journal of Obstetrics*, for February, 1873, claims the credit of first "introducing the use of both hands together, one supplementing the other, so that when either the internal or the external hand began to lose, the other would begin to gain, power."

How can these rival claims be reconciled? Ere we endeavor to do so, let us glance at my dusty little volume and trace the history of the facts it announced. Dr. Wright (I learn from Dr. Quinn, in the Cincinnati *Lancet* for June, 1878) demonstrated the practicability of bimanual version by combined external and internal manipulation, as early as 1847. The operation was formally introduced to the profession at the reunion of the State Medical Society of Ohio in 1854, and first appeared in print in the *Transactions* of that body—a copy of which is the text on which I have discoursed in this letter. Strange to say, Dr. Penrose, of your city, independently devised a similar method, which he described in the *Examiner* for July, 1855. It was not until 1860 that Dr. Braxton Hicks wrote his paper for the *Lancet*; not until 1864 that his essay on "External and Internal Version made its appearance. Dr. T. Gaillard Thomas, of New York, in his "Century of American Medicine, 1776–1876," expresses the views of the profession in this country—founded on the facts I have summarized—when he pronounces the claims of Dr. Hicks unwarranted, and maintains that the operation of bimanual version was clearly and unmistakably described by Dr. Wright.

Since commencing this letter I have been troubled with an indistinct impression that I had seen a communication from Dr. Hicks, of recent date, in which he reviews the subject. At last memory proved true; the mention of Dr. Quinn's name served as the key to the matter, for it seems Hicks wrote his letter as a rejoinder to Quinn's communication. Dr. Hicks puts the point at issue very concisely, when he says: "In an exhaustive discussion of the subject he is led to enter into the respective claims of Dr. M. B. Wright and myself as to the priority of the use of the external hand in combination with the one internally, in version." After alluding to an oversight which led him into the position he took in his first letter to the *American Journal of Obstetrics*, in 1873, he says he found out wherein he was wrong, and endeavored to correct matters in a second communication, which it seems did not fall under Dr. Quinn's eye. He then continues: "I therefore now take this opportunity of freely admitting that Dr. Wright did publish, in 1854, a plan for the production of *partial* cephalic version, which combined the use of the external hand with that of the internal." As this is the point at issue, no more can be asked of Dr. Hicks.

In conclusion let me refer to one point more characteristic of the profession of the United States in 1854, than in 1879, yet still a very noticeable characteristic. Dr. Wright might have published his bimanual method of producing version by combined external and internal manipulation for years, without gaining an adherent—aye! or even a reader—among practitioners east of the Alleghanies; but let a clinical teacher of London, Paris or Berlin make such an announcement, and at once journals are filled with com-

ments and lecturers discourse fluently on the topic, and it is not the fault of the publicity given the measure if it does not achieve success.

Let me not be accused of undervaluing Dr. Braxton Hicks. The course pursued by that gentleman shows that he not only "has taken many cities," but he has gained that greater and rarer victory which enables a man to do justice to a rival. His originality, so far as the application of combined external and internal manipulation to the production of complete or partial podalic version stands unchallenged; and surely that is crown enough for any one head to wear.

CINCINNATI.

Intestinal Worms as a Complication of Intermittents.

ED. MED. AND SURG. REPORTER:—

I was rather amused, in reading the article in the REPORTER of July 5th, as reported by C. H. Shivers, M.D., on "A Troublesome Parasite." A large number of such and similar cases come under my care every summer and fall, and my treatment is so much different from the one given by the Doctor, that I thought a pleasant criticism may benefit some of your readers.

The case in question was quotidian intermittent complicated with the presence of ascaris lumbricoides. I should have prescribed—

℞.	Quinia sulphate,	grs. xvj
	Santonine,	grs. v
	Chlorate potassa,	grs. vj. M.

Divide into sixteen doses. Give one dose every two hours during remission of fever.

During exacerbation—

℞.	Fl. extract aconite,	gtts. vj
	Fl. extract gelsemium,	gtts. x
	Sweet spirits of nitre,	℥j
	Water,	℥iv. M.

Dose, teaspoonful every two hours during the time the patient had fever. The bowels to be kept soluble by jalap and bitartrate potassa.

This treatment continued two or three days would have undoubtedly arrested the disease. If the above, aconite, etc., had been given with Dr. S.'s prescription, it would have arrested the disease, because it would have acted as sedative, diaphoretic and diuretic, thus eliminating, through those organs, much effete and morbific matter from the system. Then a small quantity of quinia would have effected a cure. But when we have symptoms of worms I invariably give santonine in small doses, with the prescription, as it is an excellent vermifuge, and more than that, it is a fine diuretic.

Probably such cases are rare in some localities, still, the physician should be fully prepared to arrest the disease at once.

I fully endorse Dr. Hamilton, of Monmouth, Ill., in the same number, when he says, "The bane of the medical profession of to-day is empiricism in high places." I think this is very true, as we read much of the current medical literature of to-day. Again he says, "It would be a happy day for us all if all generic names for diseases were struck out of existence." You are right: let us cure the lesions that produce the symptoms, filling indications, and not go by names, or follow a stereotyped treatment. Good common sense is an excellent commodity.

Redkey, Ind. J. A. HENNING, M.D.

ED. MED. AND SURG. REPORTER:—

On reading the article from Dr. Shivers, entitled "A Troublesome Parasite," published in the REPORTER, July 5th, I was reminded of a case which came under my observation not long since.

I was called at night to see Mary M., four years old, who had a high fever, with nausea, also complaining of acute pain in the side. Concluding the child had taken cold (she having been considerably exposed to the cold), I considered her trouble to be a mild attack of pleuritis. I prescribed—

℞.	Syrup. ipecac.,		
	Sp. nit. ether.,	āā	℥j
	Syrup. simp.,		℥j. M.

A teaspoonful every three hours.

Also—

℞.	Bismuth. subnit.,	gr. xxxv
	Hyd. sub. mitis,	gr. iij.

Fiat chart. No. xii. One every two hours.

On calling next morning I found the child no better, but the mother said she had passed a large worm that morning, and asked me if I did not think that was what ailed her, *i.e.* worms. I have been asked similar questions so often—indeed it seems every woman concludes, if anything ails her child, that it has "worms"—that I had been disposed to ignore the possibility entirely; nevertheless, on this occasion, I wrote the following prescription:—

℞.	Santonin.,	gr. viij	
	Hyd. sub. mitis,	gr. x.	M.

Fiat chart. No. iv. One every six hours.

The next morning as I entered the room I saw the child sitting up, looking somewhat haggard, but free from fever and also from pain: there was no more disturbed breathing. I remarked, "Mary is much better." "Yes," says the mother, "that last medicine, Doctor, did the business; look here," said she, at the same time bringing forward a vessel, "did not I tell you it was worms." True enough, we counted forty-eight worms (*ascaris lumbricoides*), from three inches to ten inches in length. Her recovery was quite rapid. WM. T. BOUGHTON, M.D.

Northwood, Iowa.

Sounds in the Ears.

ED. MED. AND SURG. REPORTER:—

In your Query and Reply column, June 5th, 1879, Dr. I. N. T. asks an explanation of the cause of the peculiarly rushing sound in the ears when the auditory canal is tightly closed by the ends of the fingers. You suggest that it is from compression of the blood in the sides of the auditory canal. I have thought about the phenomena often, and have come to this conclusion as to the cause: when the canal is closed all sounds are shut out, and the auditory nerve it enabled to take cognizance of sounds within the cranium. The roaring I consider to be due

to the return of the venous blood from the brain, the current of which is very conveniently placed to produce this effect, causing a smart vibration, on account of the tortuosity of its channel at this point. The auditory sensations become subjective. For this reason persons are not able to endure the silence of Mammoth Cave; all other sounds being withdrawn, the ears take notice of those within the body, and the sensation becomes torturing as the attention is drawn to the effect. So of persons lost in the woods. The effect can be very readily produced at any time by a person withdrawing attention from other sounds and *listening to his ears.* I notice it as I write, though there is a tumult of noises from the street. The sound is like the seething or singing of a kettle on the fire; a mere modification of that when the ears are closed with the ends of the fingers.

I explain the roaring in the ears in diseases of the Eustachian tube, from the accumulated fluid (mucus or pus) becoming a conductor of sound from the jugular vein to the auditory nerve, a quality fluids possess in a high degree.

If this theory is untenable, I suggest another, which is plausible. The effect may be due to the driving in and displacement of the tympanum by the column of confined air; hardened serum pressing against the drum has this result. In fact, by rapid tittilation of the external opening with the end of the finger, a corresponding vibration can be readily perceived within, and from its ringing metallic character it must come from the tympanum itself. E. L. DRAKE, M.D.,

Nashville, Tenn.

NEWS AND MISCELLANY.

Official List of Changes in the United States Marine Hospital Service, May 6th to June 30th, 1879.

Ellinwood, C. N., Surgeon. Detailed as member of a Board to physically examine candidates for appointment as cadet in the Revenue Marine Service, May 24th, 1879. Detailed as member of Board for the physical examination of an officer of the Revenue Marine Service, June 13th, 1879. Detailed as President Board of Examiners to convene in Washington, July 15th, 1879, June 28th, 1879.

Bailhache, P. H., Surgeon. Detailed as member of a Board to physically examine candidates for appointment as cadet in the Revenue Marine Service, May 24th, 1879.

Vansant, John, Surgeon. To proceed to New Bedford, Hyannis, and Vineyard Haven, Mass., New Haven, Conn., and Providence, R. I., as inspector, May 15th, 1879. Detailed as member of Board for the physical examination of an officer of the Revenue Marine Service, June, 13th, 1879.

Hutton, W. H. H., Surgeon. To proceed to Shreveport, La., and Vicksburg, Miss., as inspector, May 17th, 1879.

Miller, T. W., Surgeon. To proceed to Toledo, Ohio, Dubuque, Iowa, Saint Paul, Minn., and LaCrosse and Milwaukee, Wis., as inspector, May 17th, 1879. Detailed as member Board of Examiners, to convene in Washington, July 15th, 1879, June 28th, 1879.

Wyman, Walter, Surgeon. Upon arrival of Surgeon Sawtelle, relieved from duty at St. Louis, Mo., and placed on waiting orders, May 16th, 1879. To proceed to Cincinnati, Ohio, and assume charge of the Service, relieving Asst. Surgeon Keyes, June 11th, 1879.

Long, W. H., Surgeon. Detailed as recorder Board of Examiners, to convene in Washington, July 15th, 1879, June 28th, 1879.

Sawtelle, H. W., Surgeon. To proceed to St. Louis, Mo., and assume charge of the Service, relieving Surgeon Wyman, May 16th, 1879.

Smith, Henry, Assistant Surgeon. To proceed to Washington, D. C., as escort to an insane seamen, June 5th, 1879. Granted leave of absence for thirty days, June 20th, 1879.

Godfrey, John, Assistant Surgeon. To proceed to Pensacola, Apalachicola and Cedar Keys, Fla., as inspector, May 17th, 1879.

Keyes, H. M., Assistant Surgeon. When relieved by Surgeon Wyman, to proceed to St. Louis, Mo., and report for duty to Surgeon Sawtelle, June 11th, 1879.

Glazier, W. C. W., Assistant Surgeon. To proceed to Charleston, S. C., and assume charge of the Service at that port, June 20th, 1879.

Cooke, H. P., Assistant Surgeon. To proceed to Galveston, Texas, for temporary duty during the absence of Assistant Surgeon Smith, June 23d, 1879. When relieved by Assistant Surgeon Smith, to proceed to Pensacola, Fla., and assume charge of the Service at that port, June 26th, 1879.

Philadelphia Water Supply.

Dr. Charles M. Cresson, in a recent communication to the Board of Health, says:—

"The water supplied from the several Schuylkill works is now to be classed with the purest. This result has been brought about by the gradual and steady removal by the Park Commission and Board of Health of the objectionable drainages which were located so near to the pumping stations that the corrective agencies of animal and vegetable life and light failed to produce the same beneficial effects as are exerted upon the sewage which flows into the river at more distant points.

Trichinæ in Hogs.

According to the official inspection report in Chicago, of one hundred hogs examined, eight were infected with trichinæ; and it is inferred that this proportion would hold good in a much larger number. Experiments are reported, from which justifying conclusions are drawn, that trichinous hogs generally show no evidence of being "out of health."

The Yellow Fever.

On July 17th seven cases of yellow fever were introduced into the Lazaretto, below Philadelphia, from the brig Shasta, from San Domingo. The same day five new cases were officially reported in Memphis, with signs of the disease becoming epidemic.

Nervous Affections Resulting from Alcoholism.

Dr. Martin, of the *Salpetrière*, Paris, has made a series of interesting observations on nervous affections among the offspring of alcoholic parents. His results may be summed up as follows: in 83 families in which one or more members showed nervous excitability with a history of alcoholic origin, there were 410 children. Of these, 108, more than a quarter, had convulsions, and in the year 1874 169 were dead; 241 were still alive, but 83, *i. e.*, more than one-third of the survivors, were epileptic.

Cholera and Diphtheria in the East.

A Berlin dispatch of July 16th, to the *Times*, says cholera has made its appearance in the Government of Smolensk. The terrible epidemic, diphtheria, continues its ravages in Bessarabia, where a rescript of the Governor is published, ordering a universal fumigation of the dwellings and clothing of the peasantry. The rescript states that the epidemic has now been raging seven years, carrying to the grave in some districts almost all of the rising generation.

Items.

Correction.—Wm. Henry Bower, manufacturing chemist, of this city, writes us that the mixture of chlorate of potash recommended on page 39 of this volume "is evidently a dangerous one." We thank him for the caution.

—William Emerson Baker offers $200,000 to the Public Health Association of Boston, on condition that half as much more be contributed by others. The association is devoted to investigation as to house ventilation and drainage, the sale of adulterated and otherwise unfit food, and general questions concerning health.

—In New York city, last year, while the number of deaths per day varied in January from 73 to 110, of which from 27 to 50 were children under 5, in July the daily number varied from 73 to 155, of which 37 to 105 were of these little ones. The average in the heated season is nearly double what it is in the cold months.

—The Warren Triennial Prize of four hundred dollars will be awarded next year, to the best work on Original Observations in Physiology, Surgery, or Pathological Anatomy. Essays should be forwarded to the resident physician of the Massachusetts General Hospital, on or before February 1, 1880.

—The twenty-seventh annual meeting of the American Pharmaceutical Association will be held in the city of Indianapolis, Indiana, on the second Tuesday in September (being the 9th day of September), 1879, at 3 o'clock, P. M.

Personal.

—Dr. E. P. Bennett and wife, of Danbury, Conn., celebrated their golden wedding last month. A number of friends surprised them with pleasing testimonials of esteem and affection on the occasion.

OBITUARY NOTICES.

Dr. A. H. Senseny,

Of Chambersburg, Pa., died of phthisis, July 17th. He was born in the same city, in 1811, where both his father and grandfather had practiced medicine. He was a student in the office of Dr. George McClellan, of this city, and took his degree in 1835, from the Jefferson Medical College. Three years later he married, and not less than three of his sons embraced the ancestral profession. Dr. Senseny has always ranked high as a surgeon and practitioner. His name is widely known throughout the State. He was ready to serve all, the rich and the poor alike, and many thousands of dollars would not have compensated him for the skill and labor he gratuitously bestowed. He had a remarkable gift of diagnosis, and understood at a glance what was the nature of the disease before him. He was prompt and energetic in action, and these traits manifested themselves both in language and conduct.

—Dr. William K. Brown, of Brooklyn, died of apoplexy, at Narragansett Pier, July 11th. He was nearly seventy-three years of age, one of the oldest resident physicians in Brooklyn, and a prominent member of the Kings County Medical Society.

—Dr. Benjamin Bailey died in New York last week. He was one of the oldest physicians in the State, and enjoyed a large and lucrative practice. He was born in Putnam county, in 1797.

—Mrs. Elizabeth W. Horner, widow of Dr. William E. Horner, the distinguished surgeon, formerly professor of anatomy in the University of Pennsylvania, died suddenly, on July 10th, in this city.

—Dr. John Fisher, Sr., a prominent citizen of Columbia, S. C., died July 7th, 1879, in the seventy-seventh year of his age.

MARRIAGES.

LANDIS—HORN.—By the Rev. E. Stubbs, S. M. Landis, M.D., of Philadelphia, and Miss Flora E., daughter of H. J. Horn, Esq., of New York city.

NOURSE—HOMANS.—In Brooklyn, N. Y., on Thursday evening, June 26th, by the Rev. James E. Homans, Dr. Charles J. Nourse, U. S. Navy, and Emily Louise, daughter of Benjamin Homans.

ROOSA—HOWE.—In New York, on Tuesday, 8th July, by the Rev. William Adams, D.D., assisted by the Rev. Howard Crosby, D.D., Dr. D. B. St. John Roosa and Mrs. Sarah E. Howe, daughter of Mr. E. V. Haughwout.

DEATHS.

KITTREDGE.—On Sunday evening, June 22d, 1879, at the residence of his son, Ben. Kittredge, at Peekskill, N. Y., Dr. Rufus Kittredge, aged 86 years, formerly of Cincinnati, O.

PARKHURST.—In Cincinnati, Ohio, June 28th, at 6.10 o'clock P.M., Mary E., daughter of Dr. E. and Mary B. Parkhurst, aged 15 years.

SIMMONS.—On the 3d inst., at Americus, Georgia, Dr. J. R. Simmons.

VANCE.—At College Hill, O., June 27th, 1879, of consumption, Mrs. Carrie E., wife of Dr. J. W. Vance, aged 45 years.

TAMAR INDIEN,

A laxative, refreshing, and medicated Fruit Lozenge, agreeable to take, and never causing irritation. Its physiological action assures the immediate relief and effectual cure of

CONSTIPATION, CEREBRAL CONGESTION, HEADACHE, INDIGESTION, BILE, HEMORRHOIDS, etc., etc., by augmenting the peristaltic movement of the intestines, without producing undue secretion of the liquids. Unlike pills and the usual purgatives, it does not predispose to intestinal sluggishness, and the same dose always produces the same effect, that is to say, never needs increasing. These properties render "Tamar" invaluable to the weak and debilitated, and especially to ladies previous and subsequent to their accouchement. It is recommended by the most eminent Physicians of Paris; notably Drs. BELIN and TARDIEU, who prescribe it constantly for the above complaints, and with most marked success.

Prepared by **E. GRILLON,** Pharmacien de 1ère classe, 27 Rue Rambuteau, Paris. To be had of all respectable Chemists throughout the world.

PEPTODYN.

The New Digestive is a combination of the whole of the Digestive Secretions—Pepsine, Pancreatine, Diastase, etc.,

Forming an invaluable remedy in the treatment of all forms of Dyspepsia, and diseases arising from imperfect nutrition.

N. B.—*The success of this Remedy has led to several imitations of it,* which consist largely of Milk Sugar, and, as compared with Peptodyn, are of little or no real value as digestive agents.

SAVORY & MOORE, 143 New Bond Street, London.

PARIS, 1867. Prize Medal.

1868. Silver Medal.

1872. Gold Medal.

1873, VIENNA. Medal of Merit.

BOUDAULT'S PEPSINE

IN POWDER, also WINE, ELIXIR, SYRUP, PILLS, AND LOZENGES OF PEPSINE.

Since the introduction of Pepsine by Boudault in 1854, **BOUDAULT'S PEPSINE HAS BEEN, AND IS STILL CONSIDERED, THE MOST RELIABLE,** as is attested by the awards it has received at the Exhibitions of 1867, 1868, 1872, 1873, and in 1876 at the Centennial Exposition in Philadelphia.

IT IS THE ONLY PEPSINE USED IN THE PARIS HOSPITALS.

Careful tests will enable any one to satisfy himself that **BOUDAULT'S PEPSINE HAS A DIGESTIVE POWER AT LEAST DOUBLE** that of the best Pepsines in the market, and that it is really the cheapest.

It is Sold in 1 ounce, 8 ounce, and 16 ounce Bottles.

Beware of so-called French Pepsines bearing fictitious names, and prescribe Boudault's only.

BLANCARD'S PILLS

OF UNCHANGEABLE IODIDE OF IRON.

Blancard's Pills of Iodide of Iron are so scrupulously prepared, and so well made, that none other have acquired a so well deserved favor among physicians and pharmaceutists. Each pill, containing one grain of proto-iodide of iron, is covered with finely pulverized iron, and covered with balsam of tolu. Dose, two to six pills a day. The genuine have a *reactive silver seal* attached to the lower part of the cork, and a green label on the wrapper, bearing the fac-simile of the signature of

Blancard

Pharmacien, No. 40 Rue Bonaparte, Paris.
without which none are genuine.

BEWARE OF IMITATIONS.

E. FOUCERA & CO., Agents,

NEW YORK.

PHOSPHOROLE.

PHOSPHORUS and COD-LIVER OIL

have now an established position throughout the civilized world as important therapeutical agents. A *perfect combination* of the two has long been a desideratum, since they are both of value in the same disorders, while the cases in which one is demanded and the other contra-indicated are exceedingly rare.

The combination in PHOSPHOROLE has the twofold advantage of furnishing *the best possible form* for the administration of *phosphorus*, and *a more effective form* for the administration of *cod-liver oil*.

With regard to the former, it has been decided by the highest chemical and medical authorities that *phosphorus* should be administered *in a free state*, and in a vehicle which ensures its *perfect diffusion*, its *absolute unalterability*, and, as far as possible, its *prompt assimilation* without the gastric irritation to which the ordinary methods of exhibiting the agent give rise. It is well known that pills, emulsions, solutions in ether, chloroform, vegetable oils and resin, etc., have all failed to fulfill one or more of these conditions. Even an ordinary solution of phosphorus in cod-liver oil would not answer the purpose in all respects. We claim, however, that PHOSPHOROLE completely satisfies all the conditions. From the method of preparing it, in an atmosphere of dry carbonic acid, the phosphorus is *entirely dissolved without oxidation*, and by our mode of manipulation *a positive uniformity of strength* is ensured. It is then promptly bottled and sealed, and its *stability and permanence* thus secured. The exact amount of phosphorus in each dose is known, its efficiency is ensured, and the irritant effects upon the stomach are reduced to a minimum by the blandness of the oil. As a means then of administering *phosphorus* in the many cases in which it is indicated as a *nervous tonic and stimulant*, it is claimed that PHOSPHOROLE is the best attainable in the present state of our knowledge.

The value of *cod-liver oil* in phthisis is so familiar to the physician that it is needless to dwell upon it. But the value of *phosphorus* is also universally recognized in this disease, especially when complicated with nervous derangements. The *combination* of the two therefore furnishes a more effective form for the administration of cod-liver oil in the great majority of cases in which that remedy is indicated, and one which will at once commend itself to the profession.

A dose of two teaspoonfuls of PHOSPHOROLE contains $\frac{1}{100}$ of a grain of phosphorus. This dose, when given after a meal, is effective, and not very liable to interfere with digestion. *Phosphorus is cumulative in its action, and should be administered with watchful care.* About $\frac{1}{12}$ grain is considered the largest safe dose, and we rarely need go higher than $\frac{1}{20}$ or $\frac{1}{80}$ of a grain. At the very first appearance of the smallest gastric derangement, the exhibition of phosphorus should be stopped.

PHOSPHOROLE is handsomely put up in pint bottles only, and may be obtained at all first-class druggists throughout the United States.

Descriptive Circulars furnished upon application.

SOLUBLE

Pills and Granules.

UNEQUALED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

1. The best materials are used in their manufacture.
2. No article required by a formula is omitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.

Our list of Pills and Granules embraces those made according to the formulæ of the U. S. Pharmacopœia; also most of those in common use among the profession.

Original Department.

Lecture.

AURAL THERAPEUTICS.

A Clinical Lecture, delivered February 27th, 1879,

BY LAURENCE TURNBULL, M.D.,
Aural Surgeon, Jefferson College Hospital.

Reported by Charles W. Karsner, M.D., Assistant to the Aural Department Jefferson College Hospital.

Gentlemen:—The reason is very often given for not recognizing aural surgery as a special department, that its advocates do not cure the many chronic cases of deafness that afterward float about from one practitioner to another, informing each that they were under the care of a specialist, without being improved. Gentlemen, is not this the case with all chronic diseases, no matter which organ of the body is affected, except it be a functional disorder? Every day of our life we hear of cases of diseases of the brain, eyes, lungs, heart, liver, kidneys, spleen, bladder, uterus, ovaries, and muscular apparatus, being discharged as incurable or to die, from the hands of the best and most learned in diagnosis, unexcelled in their knowledge of anatomy, physiology, and pathology; even experts in physical diagnosis. In the various acute affections of the human ear, I can refer with pride to the record on our clinical books, and show as good results as in any other of the out-door departments. And in our chronic cases of diseases of the ear, where there were no absolute changes, such as destruction of the organ or alteration of tissue, which so frequently follow long protracted disease, the result of our treatment will be found equal to any other department in the short period it has been in operation. (See report submitted to the Board September 30th, 1878.) A glance at the various tables in my "Manual of Diseases of the Ear,"* pages 56, 57, 58 and 59, from various authors, and our best authorities in aural surgery and medicine, will serve as a guide to the frequency of aural disease, with some results of treatment. I will briefly extract a few facts from them: of six hundred cases carefully recorded, in Howard Hospital and in private practice, the number cured was 241, improved, 194. In a similar table by Dr. Schwartze, of Halle, of 322 cases, 145 were cured and 122 improved. Of Dr. Moos's cases (chronic aural catarrh), 100 in all, there were 17 cured and 64 improved; and Prof. Gruber cured 326 cases and improved 128, in 763 cases.

A view of tables of cases will show a great preponderance of chronic affections, very many of them the result of neglected acute attacks, that were manageable if they had been diagnosed and treated in their early stages. The duration of the six hundred cases before referred to will give an idea of the neglected condition of many of the cases received by us for treatment, and our results will compare favorably, we think, with the condition of the patients when received:—

* J. B. Lippincott & Co., Philadelphia.

In all diseases the prognosis is a matter of the gravest importance; and young gentlemen, you who are about to graduate, see that you make this a matter of careful study, and commit to memory the prognosis in most of the prominent diseases, so that you may inform your patient as to the chances, based on carefully recorded experience of others, and after a time, when you have had a sufficient number of cases, on your own account. I will refer you to my teachings on this subject, and will advise, in passing, not to give a hasty prognosis in any case, for it will depend largely upon the severity of the attack, the general health of the individual, the hereditary tendencies, and upon the duration. The great majority of practitioners, and we may say, with truth, even many general surgeons, are not well informed as to the nature of obscure diseases of the ear, and some of them are not provided with proper mirrors or a speculum to examine the ear, nor with a suitable text book, so as to understand how the ear should look when diseased (at this point the lecturer exhibited several illustrated works on diseases of the ear). Indeed, but few can tell a purulent otitis of the middle ear, with perforation of the membrana tympani, from a diffuse otitis of the meatus, and they constantly confound it with chronic suppuration of the external auditory canal, under the old term of "otorrhœa." Again, in summing up from my tables, the cases show that, instead of external disease of the ear, the majority of cases are serious and dangerous diseases of the internal and middle ear, for we find there are 742 cases of chronic inflammation and suppuration of the middle ear, to 138 cases of chronic inflammation of the external auditory canal. I am constantly receiving from well educated graduates of our own and other schools cases which, most unfortunately for the patients, illustrate this want of knowledge. A few lectures and demonstrations on the patients received at our clinic would most effectually prevent such dangerous mistakes.

I will now pass to the consideration of a few of the remedies which I find especially valuable in aural disease, and will endeavor in the brief time at my disposal to show as many cases as I can, so that you may not make such mistakes as those to which I have referred.

The action of aconite on the circulation and respiration is somewhat remarkable; after a few doses, of one to five drops of the tincture of the root, or the $\frac{1}{140}$ of a grain of the nitrate of aconitia, the number of the heart's beats are reduced to one-half the normal standard, say to forty in the minute, while it renders the breathing very much slower. Aconite affects the muscular substance of the heart and also the ganglionic nerves. Now, how will aconite act so as to be useful in ear diseases? In acute catarrh of the middle ear, with tonsillitis, in which the skin is dry, hot and burning, its judicious and careful use causes the skin to become moist, and subsequently bathed in a profuse perspiration. Acute otitis media, associated with pharyngitis, rarely fails to succumb in twenty-four hours, and the tonsils, from being livid, red, glazed and dry, will become reduced in size and bathed with mucus. And then, by the proper use of the spray or gargle of astringents, and nitrate of silver, with the Politzer air douche, the noises, pain and deafness will disappear. Another form of ear disease is chronic catarrh of the middle ear, in which the patient is very liable to catch cold, as it is often expressed. This is followed by subacute inflammation of the fauces, which become swollen, red and dry, this condition passing into the tonsils, uvula, arches of the soft palate, and up the Eustachian tubes or downward to the chest. This condition may have existed for years, with constant relapses. the whole appearance of the throat and orifices of the Eustachian tubes never becoming natural, but often clogged with tenacious mucus, or even by pus, also with patches of enlarged follicles. At other times the disease is found chiefly in the middle ear, in which, after the acute stage, there still remains fluid. This condition will be benefited by aconite, but it must be combined with belladonna or jaborandi. The dose is from one to three drops of the tincture of aconite with five drops of the tincture of belladonna, every three hours. The success of this treatment will depend upon the care with which it is followed up by a careful hardening and cleansing of the parts by means of cold outside the throat and astringents inside; above all, with the free use of quinine, in conjunction with nourishing food and outdoor exercise in fine weather. Now, there is a certain caution to be used in the use of aconite and belladonna; do not exceed the full dose in the twenty-four hours, nor trust the patient or nurse without careful watching, as aconite is an exceedingly powerful poison; one-twelfth of a grain of the crystallized alkaloid is sufficient to kill an adult. In a case of recovery from a poisonous dose (one ounce Fleming's tincture), the agents employed were twenty minims of the tincture of digitalis, hypodermically injected, and after twenty minutes, the man having revived sufficiently to swallow, a

fluid drachm of the tincture of digitalis, with ammonia and brandy, was given to him, and repeated twice within the hour, and the man recovered. The treatment of belladonna poisoning is evacuation of the stomach, opium and stimulants. Externally heat is applied, with flagellations, artificial respiration, etc.

Digitalis influences the ganglionic nerve centres of the heart and capillaries in such a way as to impart steadiness and force to the muscular fibres of the former, and improved elasticity to those of the latter, thus causing the streams of circulation to move with an equable and natural current into and out of every organ. By this regulation of the cerebral current of circulation various functional disturbances of the brain, ideal as well as sensory, like delirium, pseudopsia, tinnitus aurium, are ameliorated or permanently removed. *Quinine*, if the dose is large enough, acts on the auditory nerve centres, producing temporary tinnitus aurium or subjective sounds, which are modified by the use of hydrobromic acid in combination. It is also true of quinine that it is curative in certain forms of ear diseases of an intermittent character, or malarial neuralgia of the third branch of the fifth or trifacial nerves. Also in distressing tinnitus aurium arising in certain furunculous disease of the ear, in which the noises are a reflex irritation or action of the nervous system. *Strychnia* and its salts are agents which act in producing reflex action of the nervous system, and especially the spinal nerves; by its use loss of power or atrophy of the auditory and other nerves which supply motor and sensory action to the ear is relieved or improved. Strychnia is best administered by hypodermic injections of the sulphate, beginning with one-sixtieth of a grain daily, and gradually increasing, till by the end of a month the system of the individual may become, as we say, so tolerant as to bear one-quarter of a grain, yet we have known at such a time a slight contact or blast of air to produce convulsions or cause complete rigidity. The centres of the frontal lobes and the cerebral sensory centres, both of sight and hearing, are less amenable to the influence of strychnia than the spinal cord.

The *bromides of potassium, sodium, lithium and ammonium* exert upon reflex action an influence the opposite of that induced by strychnia; in diseases of the ear they modify it, and their influence extends to the sensory and ideal centers. It is possible by these agents to dull without destroying the reflex sensibility of the nervous system, and to act directly upon the cerebrum and spinal nerves, so that the visual and auditory centres perceive sights and sounds, and report them to the frontal lobes, where they are received with indifference. Another phenomenon which follows the administration of the bromidal preparations is that of sleep. This has been produced by its action on the vasomotor nerves, producing contraction of the capillaries, and especially so of those of the brain. Bromide of potassium in very large and repeated doses, on account of adynamia, which it sometimes causes, must frequently be suspended. In addition to weakness, retardation, and irregularity of cardiac action, the bromide of potassium may give rise to præcordial pain, or will sometimes improve the appetite and nourish the patient. In such cases it should be taken at meal times, or after, in a tumbler of milk. Bromide of sodium is a milder preparation, more easily borne by the stomach, and is to be preferred in the cases of nervous women, old people, or children, as it can be added to soup in the place of common salt. This can be employed in the various forms of nervous affections of the ear, in the dose of 15 to 30 grains in solution with syrup of red rose, as it is readily deliquescent, and will not keep in powder. The bromide of ammonium is a more stable preparation, and is best given with syrup of orange peel, in doses from one half to two drachms daily. This acts well in all spasmodic affections of the throat, larynx and glottis in children, as well as in hysterical persons, who often suffer from subjective noises in the brain and ears. Then there is another of the class which is termed the brominated camphor. This, like the hydrate of chloral, is an antidote to strychnia in doses of fifteen to thirty grains; also useful in nervous palpitations of the heart in $3\frac{1}{2}$ to $4\frac{1}{2}$ grains several times a day. It has also been found useful in sexual excitement and pollutions, attended with various noises in the head or ears, but in very stubborn cases the bromide of potassium with opium or tincture of veratrum viride (two or three drops on sugar, continued until slowing of the pulse is attained) acts sometimes much more satisfactory. In irritation from cold of the throat, nose or bladder, in doses of from three to eight grains, we have found the bromated camphor to remove the annoying difficulty. The *bromide of zinc* is to be prescribed only in pill, from $1\frac{1}{2}$ to 2 grains, and gradually increased to 6 grains. It is found particularly useful in hysterical muscular spasm of the intrinsic or extrinsic muscles of the ear.

Chloral hydrate is very valuable in the pain of megrim, clavus, sick headache, in five-grain doses every three hours. This agent is also very

useful when associated with the bromides in neuralgia of the fifth, also the occipital and auricular nerves of the ear.*

Exhibition of Cases of Ear Disease.

The first set of cases which the Doctor brought before the class were diseased conditions of the auricle, as fibrous and other tumors, eczema, hemorrhagic and polypoid growths of the meatus, furunculous abscesses, with desquamative epithelial inflammation, and compared these, showing them the ordinary form of impacted cerumen, proving how very important it was to make a correct diagnosis, which, he stated, could best be accomplished by having seen and examined for themselves each variety of ear disease.

The second series of cases consisted of acute otitis media, catarrhal and purulent, occurring as the result of cold and of the exanthemata, the first occurring in the adult, the second in children. The new method of treatment was then shown the class by means of the "Gruber cones" of gelatine and glycerine, which he considered a great improvement over the old form in the hands of the patient.

The third class, six in number, which the Doctor exhibited, were cases of each variety of perforated membrani tympani, with disease of the middle ear, from the minute point of perforation to the case of almost entire loss of the membrane; also a rare case in a young lady who had a double perforation in one ear, and a single perforation in the other, which followed pneumonia. The lecturer brought one case of perforation before the class, who was able when the class was very still to pass the air so audibly through the Eustachian tube and perforation as to be heard by almost all present. Three clinical assistants went round the class, and with the proper speculum and mirror were able to show the students most of these interesting cases. The great importance of careful cleansing of the ear was dwelt upon, and all the most approved apparatus were shown and their mode of use explained.

A fourth class of cases were then exhibited, of acute and chronic disease of the ear without perforation, and the Doctor dwelt at some length upon alcohol and tobacco disease of the throat, Eustachian tubes, and middle ear, and in an illustrative case showed the decided improvement from giving up entirely the use of the *weed*, and the advantages of injections of warm solutions of glycerine in water into the middle ear by means of the Eustachian catheter and air douche.

At the conclusion of the lecture, which was listened to with deep attention, the Doctor dwelt upon the importance of each of the new graduates being prepared to treat diseases of the ear properly; because the first case which will present itself on opening an office may be an adult suffering from acute disease of the ear, or some little one on the very brink of convulsions from the same cause, which, if not recognized, might be bled and blistered for disease of the brain.

* For details of the action of this drug the Lecturer referred to his "Manual of Anæsthetic Agents, and their Employment in the Treatment of Disease," second edition, p. 209, published by Lindsay & Blakiston, Philadelphia, 1879.

Communications.

THE RELATION OF AGE AND THE SEASONAL DEATH RATE.

BY T. S. SOZINSKEY, M.D., PH.D.,
Of Philadelphia.

In an article published in this journal some time ago, I presented abundant evidence to show that the death rate in the United States as a whole and in the city of Philadelphia varies with the season of the year. I now propose to determine whether the seasonal death rate varies also at different periods of life, and try to find out the reason or reasons for any variations which may be found to exist. In studying this interesting and by no means unimportant subject, nothing of consequence could be gained by dwelling on statistics of the nation at large, even if such were accessible. It is proper to limit the territory from which the mortality statistics are drawn, so that the meteorological conditions of different parts of the year may be kept as free as possible from conditions which may be called climatic, using this term to express the general yearly character of the weather at different places. For purposes of comparison the meteorology and the mortality of particular places might be studied to some advantage; but in undertaking to make comparisons of this kind one would be very liable to be misled, for the local physical conditions, the length of time a place has been settled, and the race, density, habits and customs of the population, have much to do with the death rate. A suitable standard for comparison is to be found in the average mortality of the place for a few years past; and this is the one I will adopt. I say the average for a *few* years past, because the average for a long series of years includes the effects of change in the local conditions, which may be very important in character, not to mention change in

the ways and nature of the population. My meaning will be clear when I say that the relative mortality from different diseases is not at all the same now as it was a number of years ago, in most large cities, although the ordinary meteorological data furnish little or no proof of change. Thus, in London malarial fevers, in the time of Sydenham and long afterward, were the great perennial scourge of the population; while, at present the number of deaths from these diseases is very small, the cause being mainly better drainage and sewerage. A somewhat similar statement might be made in regard to Philadelphia. The relative mortality of the months at present compared with what it was fifty or a hundred years ago must be attributed largely to changed local sanitary conditions. How great the difference is in London I pointed out in my essay referred to above, and in Philadelphia it is also very marked within the last three quarters of a century. In his valuable analysis of the mortality statistics of this city for twenty years, beginning with 1807, the date when systematic registration of deaths and their causes began, which appeared in 1827, in the first number of the *American Journal of Medical Sciences*, Dr. G. Emerson found the order of mortality of the months to be—beginning with the one in which it is greatest: August, July, September, October, June, March, April, November, January, December, May, February. It will be noticed that the order for that period is very different from what it has been of late, by comparing it with the order for the fifteen years ending with 1875, which is as follows: July, August, March, January, April, May, December, February, June, October, September, November.

Of course, it will occur to the reader that, as hinted in the article referred to above, it is impossible to expect the mortality at different periods of the year to reflect precisely the state of the weather, for the reason that man's intellect enables him to make more or less successful efforts to place himself on agreeable relations with external conditions by regulating his clothing, shelter, food and habits in general. It is only in the vegetable kingdom that cause and effect are here at once apparent. In the forming buds, blossoms and fruit, and the disappearance of these, we can in our trees note the coming and going of the seasons, and from the flora of a place tell a good deal about its climate. I am impressed with the failure of ordinary human care to entirely circumvent the effects of change of atmospheric conditions, by some leafless tea-plants which are before me as I write. Although they have been well attended to since the cold weather set in, it is doubtful whether there is now sufficient vitality in them to respond to the reviving breath of spring. Whatever seasonal difference exists in the human death rate is expressive of the degree of failure of the race to duly antagonize atmospheric vicissitudes, either direct or indirect. It is well to say that under the head of atmospheric vicissitudes may rightly be included all changes in the atmosphere, whether of composition or other qualities, due to gaseous and other emanations from the earth. Until we can and do systematically recognize these modified states of the air, arising from local conditions, medical meteorology will lack much of being exact; and while this is so medical science will not advance as it should. Here I would observe that the practical medicine of our day takes far too little notice of the media in which people exist; it is confined far too exclusively to efforts to change the state of the system through the forces that are at play within, and in opposition to those that are antagonizing these from without. A knowledge of the philosophy so admirably expounded by Herbert Spencer would be of use to physicians. I cannot help quoting several pregnant passages from him. Says he (*Principles of Biology*, 1864), "Change of every order is toward equilibrium, but we have also the truth, which holds throughout the organic world, that life itself is the maintenance of a moving equilibrium between inner and outer actions—the continuous adjustment of internal relations to external relations; or the maintenance of a correspondence between the forces to which an organism is subject and the forces which it resists." A definition of life quite similar to that of Bichat, which is that "life is the sum of the functions which resist death." Again (ibid.), "Those changes which enable a species to live under altered conditions are always toward equilibrium with the altered conditions. . . . A factor which does not act continuously or frequently on the individuals acts continuously on the species as a whole, either destroying such of the members as are least capable of resisting it, or fostering such of the members as are most capable of taking advantage of it."

Taking the years 1875, 1876 and 1877 as the period for my study of the relations of the meteorology to the mortality in Philadelphia, I will begin by giving the former, and in the form of monthly averages for the three years on the average, and for the last of these alone—gaining in this way data for important comparisons. Monthly averages being more definite than quar-

terly ones, are better; and it would be still better perhaps, to make them shorter; but the influence of meteorological changes not being immediately manifest in the death rate, it is well to deal with considerable periods, periods long enough to cover at least the usual length of time from the inception to the crisis of acute diseases. Many of the deaths of some weeks might properly be referred to influences at play a week, or month, or longer before. It would be far more instructive to study the relation between the prevailing meteorology and the sickness rate than the death rate, but unfortunately the former can be but very imperfectly known. If all physicians could and would scientifically study the meteorological influences under which the disorders of their patients originated, preventive medicine would doubtless reap great advantage from the practice.

I do not pretend to be able to give the meteorology of Philadelphia in anything like a complete form. No systematic observations of the varying amounts of electricity and other more or less active agents in the air are made. Most of the figures I will give are calculated from data furnished by the U. S. Signal Service officers, and may be taken as correct so far as they go. It is well to remember, however, that observations made at an altitude of thirty or forty feet do not indicate the character of the air near the ground, which is most subject to variations; let no man delude himself by supposing that the results of such observations constitute anything more than approximate medical meteorology. Each ward, each square, each house in the city has a meteorology of its own, which every physician seriously interested in etiology, yes, and therapeutics, should study.

The following table gives the maximum, the minimum and mean of the thermometer (Fahr.), as determined by observations made at 7 A.M., 2 P.M. and 9 P.M. daily, for each month of the year for the three years, on the average, and for the last of these alone:—

	MAX.	MIN.	MEAN.	MAX.	MIN.	MEAN
January	53.5	6.0	30.7	49	8	28.4
February	59.6	7.0	32.3	60	16	36.9
March	64.6	12.0	36.8	67	15	38.2
April	75.0	26.6	48.2	80	30	50.0
May	88.0	39.6	61.0	90	41	60.7
June	93.6	52.3	72.1	93	54	71.7
July	95.6	60.6	77.0	95	61	77.8
August	89.6	59 0	74.0	93	63	75 5
September	87.3	46.3	64.9	84	48	66.8
October	76.0	35.6	53.9	79	41	57.4
November	69.0	17.6	43.9	68	22	46.6
December	59 0	10.0	33.2	63	22	40.6

The following table gives the maximum, the minimum and the mean of the barometer, as determined by observations made at 7 A.M., 2 P.M. and 9 P.M. daily, for each month of the year for the three years, on the average, and for the last of these alone:—

	MAX.	MIN.	MEAN.	MAX.	MIN.	MEAN.
January	30 682	29.481	30.185	30.647	29.243	30.163
February	30 733	29.267	30.117	30.565	29 402	30.084
March	30.537	29.221	30 048	30.582	29.120	30.001
April	30.458	29.504	30.002	30.403	29.419	29 983
May	30.388	29 5 6	30.014	30.389	29.460	29.997
June	30.250	29.675	30.009	30 293	29.611	29.997
July	30.265	29.700	29.980	30.264	29.703	29 953
August	30.265	29.737	30.013	30.223	29.689	29.954
September	30.346	29.619	30.032	30.328	29.718	30.077
October	30.512	29.441	30.065	30.532	29.391	30.062
November	30.587	29.463	30.067	30.618	29 314	30.127
December	30.688	29.266	30 082	30.630	29.342	30.179

The following table gives the mean relative humidity and the rainfall (and snow melted), in inches, for each month of the year for the three years, on the average, and for the last of these alone:—

	HUM.	RAIN.	HUM.	RAIN.
January	72.3	2.32	76	2.62
February	66.3	3.02	64	.84
March	68.3	4.40	68	3.40
April	57.3	2.55	60	2.66
May	56.6	2 30	54	1.10
June	65.6	3.88	67	5.22
July	66.3	4.95	70	5.53
August	71.3	2.68	69	.66
September	68.6	4.71	70	2.74
October	68.0	3.00	74	6.52
November	70.3	3.95	72	5.14
December	74.0	1.86	73	.83

The following table gives the number of times the wind was found blowing from each of the directions named, as observed at 7 A.M., 2 P.M. and 9 P.M. daily, for each month of the year for the three years, on the average, and for the last of these alone:—

The following table gives the time the sun is above the horizon, per month, calculated for the year 1879:—

	HOURS	MINS.
January	300	13
February	298	4
March	370	35
April	398	21
May	445	45
June	448	3
July	454	59
August	425	2
September	373	41
October	345	13
November	299	7
December	290	31

These tables give all the data necessary to convey a complete understanding of the ordinary meteorology of Philadelphia. It would be interesting to point out in detail the influences which determine the climate of this city, but I cannot enter fully into the complicate subject now; a few brief statements bearing on it must suffice here.

The city of Philadelphia, which includes the whole county of the same name, an area of 82,700 acres, is situated in north latitude 39° 57′, and west longitude 75° 10′, and had in the Spring of 1876, the time when the last census was taken, a population of 817,448. It is located on and west of the flat tongue of land bounded by the Delaware and Schuylkill rivers, which unite about three miles south of the limit of the built-up portion, to form the Delaware bay, which is navigable by the largest steamers. These rivers are large; the former, near its mouth, being almost a mile, and the latter about half a mile in breadth. In both, near their union, the tide is very observable; in the Delaware the rise averages five feet, and is observable over thirty miles above the city. The water is fresh for over fifty miles down the bay, which is one hundred miles in length. The site of the city is from twenty to fifty feet above the level of the sea, from which it is distant in a bee-line eastward about fifty miles, and consists geologically of tertiary deposits resting on primitive rocks. It was covered, for the most part, with a heavy forest when the city was founded (1682); but doubtless it was overswept by the sea at a no very remote date in geological time. Philadelphia, however, is perhaps more dependent on its relative than its actual geographical position and its site, for its climate. The immense territory to the west, southwest and northwest, and the ocean with its great current, the Gulf Stream, to the east and southeast, are very potential in their influence. This great northeastern current, the water of which is from fifteen to twenty degrees warmer than that which surrounds it in the 40th parallel of latitude, has much to do in bringing about the dry, cold northwesterly winds which are so marked a feature of the climate of Philadelphia during the colder half of the year; and this feature would be more marked if the course of the stream were the same in winter as in summer. In winter it does not come so close to our coast as it does in summer, and in this way lets a considerable current from the north sweep into the west of it, which not only diminishes the force and frequency of the northwesterly and westerly winds, but not unfrequently succeeds in making itself felt in the form of a northeast wind, which is anything but agreeable in nature. In the frequency of southwesterly winds in the warmer half of the year, in Philadelphia, the Gulf Stream becomes again apparent. In the Atlantic States it is rare for a storm to take any other course than northeasterly, a fact pointed out by Franklin; when it does occur, it is generally in the autumn, when the air of the interior of the continent tends to be comparatively very rarefied. Southwesterly storms are mostly preceded by northeasterly winds and rain, and followed by westerly winds and clearing weather.

The direction of the wind has much to do in determining the humidity, and to some extent the rainfall. Northerly winds are dry as a rule, while southerly winds are the reverse. Of course a precipitation of rain or snow is due to a reduction of the temperature of the air to or below the dew point, and this occurs either from the air

ascending to a higher and consequently a colder plane, or the immediate contact of two or more bodies of air of temperatures sufficiently different to result when united in a figure below the dew point. The centre of the area of low barometric pressure is where the bulk of precipitation will occur. Did space permit, it would be profitable to dwell at length on the relation of temperature to humidity—a branch of meteorology which has not received the attention which it deserves. In Boyle's *Memoirs for a General History of the Air* (1725) occurs this seemingly paradoxical statement: "I am informed by two gentlemen of the province of New Hampshire, New England, that both the coldest wind of that country in the winter and the hottest in the summer is the northwest." Thanks to the labors of Prof. Tyndall, in regard to the diathermancy of different gases and vapors, begun in 1861, this can now be easily explained. While oxygen and nitrogen and pure air itself are almost entirely diathermous, the absorptive power of moisture is very great. It seems that a molecule of aqueous vapor has 16,000 times the absorptive power of an atom of oxygen or of nitrogen; and carbonic acid, marsh gas, ammonia, etc., are also extremely absorptive. Now, when the sun shines on an atmosphere that is dry, his rays pass through it in all their power, but when the air is damp the rays are much weakened before they reach the earth. On the other hand, when the air is dry, the heat from the earth radiates into space much faster than when it is moist. The importance of these facts from a medical standpoint is very great. All the agents just mentioned as powerful absorbents of heat are found in greatest abundance near the earth; consequently, they absorb a large amount of the heat radiated from the earth —which, it must be borne in mind, is the chief source of the heat diffused in the atmosphere. Usually over ten per cent. of the heat from this source is absorbed within ten feet of the ground, a fact which makes it seem rather absurd to place meteorological instruments at an altitude of forty or fifty feet, so far as sanitary science is concerned. The acute intellect of Bacon came near to seeing through this matter of the relation of temperature to humidity, as indicated by the following interesting passage from his *Natural History*: "Starlight nights, yea, and bright moonshine nights, are colder than cloudy nights. The cause is the dryness and fineness of the air, which thereby becometh more piercing and sharp; and, therefore, great continents are colder than islands." I believe that a careful study of this subject would enable that excellent student of meteorology, Mr. Lorin Blodgett, to understand why the heat of summer in the greater portion of the United States rises higher than it does in most tropical countries, as well as why the cold of winter becomes at times so great—facts which he, in a paper read before the American Public Health Association, in 1873, pronounced to be inexplicable.

I will not make lengthy comments on each of the meteorological tables; they will be clear enough to every one of ordinary intelligence. I will confine myself to a few running remarks.

The order of succession of the months, according to the average temperature, is as follows, beginning with the one in which it is the lowest: January, February, December, March, November, April, October, May, September, June, August, July. The order of the months according to range of temperature, is as follows, beginning with the one in which it is greatest: February, March, November, December, April, May (same as last), January, June, October, September, July, August. The highest temperature recorded was in July, 1876, when it went up to 100°; and the lowest was in January, 1875, when it went down to —5°. This gives a difference or range of 105°. The order of the months, according to temperature, is the same for 1877 as for the three years, on the average, save that March comes in advance of December. The order, according to range, differs considerably; it is as follows: March, April, May, November, February, January, December (same as last), June, October, September, July, August.

I may remark of the table of the barometric pressure, that the instrument used in making the observations stands 46.9 feet above the level of the sea, for which, as well as the temperature and instrumental errors, the readings have been corrected. As might be expected, the pressure is less in summer than in winter. At all seasons of the year it, as a rule, falls when the wind becomes southerly, and rises when it becomes northerly. The following is the order of the months, according to the degree of pressure, beginning with the one in which it is greatest: January, February, December, November, October, March, September, May, August, June, April, July. The following is the order, according to the range, beginning with the one in which it is greatest: February, December, March, January, November, October, April, May, September, June, July, August. The order for 1877, according to temperature, is as follows: December, January, November, February, September, October, March, May, June (same as

last), April, August July. The order, according to range, is as follows: March, January, November, December, February, October, April, May, June, September, July, August.

The relative humidity or degree of saturation of the air is of greater sanitary significance than the rainfall, but both are important. In a city the rain washes the air, as well as the streets and sewers, of many impurities, the presence of which would be prejudicial to health. It should be remembered that the relative humidity is not always, or even generally, high when rain falls, which is easily understood when it is borne in mind that the state of the higher atmosphere may be and is very different, generally, from that of the lower. December is the month in which the relative humidity is highest, but it is the one in which the rainfall is least. The following is the order of the months, according to their mean relative humidity, beginning with the one in which it is highest: December, January, August, November, September, March, October, February, July (same as last), June, April May. The following is the order for 1877: January, October, December, November, September, August, March, June, February, April, May.

The following is the order of the months according to the rainfall, beginning with the one in which it is greatest: July, September, March, November, June, February, October, August, April, January, May, December. The following is the order for 1877: October, July, June, November, March, September, April, January, May, February, December, August.

The table of the winds does not indicate the occurrence of "calms," which were observed on two or three occasions in the autumn of each year; these I have placed under the heading to which I suspected them to be most closely related. The prevailing direction of the wind each month of the year is as follows: In January, northwesterly; in February, northwesterly; in March, northwesterly; in April, northerly; in May, southerly; in June, southwesterly; in July, westerly; in August, southwesterly (easterly as often); in September, easterly; in October, southwesterly; in November, northerly; in December, northwesterly. For 1877, the prevailing wind in January was westerly; in February, northerly; in March, northerly; in April, easterly; in May, northerly; in June, southwesterly; in July, westerly; in August, westerly (southwesterly as often); in September, southwesterly; in October, southwesterly; in November, southwesterly; in December, northeasterly (northwesterly as often). The north wind is commonest in April and rarest in June; the northeast is commonest in September and rarest in June; the northwest is commonest in February and rarest in June; the west is commonest in June and rarest in March; the southwest is commonest in June and rarest in February; the southeast is commonest in April (same in September) and rarest in December; the east is commonest in August and rarest in October; the south is commonest in August and rarest in January. The relative frequency of the winds is indicated by the following figures: North wind, 151.1; northeast, 108.8; northwest, 195.3; west, 180.0; southwest, 184.7; southeast, 35.1; east, 166.2; south, 71.8. The south, the east, and the southeast are, as a rule, very moist winds; next comes the northeast, next the southwest, next the west, next the north, and last of all the northwest. The east wind blows on the great majority of the occasions of snow or rain during the first four months, and on a majority of the whole year. A sudden veering of the wind from a southerly to a northerly point of the horizon is generally attended with more or less of a precipitation, and the same is true when it veers from a northerly to an easterly direction. The wind blows only occasionally as long as twenty-four hours in one direction; four days was the longest period in the year 1877.

The order of the months, according to the number of miles of wind, is as follows, beginning with the one in which it is greatest: March, April, December, February, November, May, January, October, June, July, September, August. The order for 1877 is as follows: March, November, April, December, February, May, October, January, June, July, September, August. It must not be forgotten that February has three days less than some of the other months. The northwest wind is, as a rule, the most violent. The great storm of October 23d, 1878, which attained the, perhaps, unprecedented velocity of seventy-five miles an hour, was from the southeast by east.

I may digress here to observe that the direction and force of the winds are very important from a medical standpoint, and are far less studied than they should be. How many physicians in Philadelphia are prepared to say what the physiolcgical effects of a change from a northerly to a southerly wind in January are, or the effect of the same change on the prevalence of smallpox or any other disease? The early cultivators of medical science were fully alive to the importance of winds. In the "Aphorisms" of Hippocrates the subject is dwelt on at length

and instructively. The character of each of the winds, however, both in Greece and Rome, is very different from what it is in nearly all sections of the United States. In his work, "De Medicina," Celsus gives these broad generalizations, which still hold good, at least, in the south of Europe: "Generally, in every place, a wind that comes from the inland parts is healthful; one from the sea is sickly." A southerly wind coming off the sea, being warm and moist, is oppressive. It is worth while to quote here the following passage bearing on this subject, from the work of Boyle, referred to above: "It is evident that, according to the vehemence or slackness of the wind, and the places from which and to what quarter it happens to blow, various effects ensue, especially in animate bodies; and this is not only as it is attended by cold and heat, moisture and dryness, but considered as an aerial stream, whereby it fans the places through which it passes, expels the stagnant air and introduces fresh; hence it doubtless may contribute to many changes in the health of animals, but especially in the tender sort of them." One broad generalization which it is well to bear in mind is this: southerly air is generally moist, while northerly air is dry. This, with their differences in temperature, furnishes a clue to the explanation of the following rather emphatic remarks taken from Bacon's interesting *Natural History of Winds:* "While the south wind blows men's breath grows ranker, all creatures' appetites decay, pestilent diseases reign, men wax more slow and dull; but when the wind is northwardly men are more lively, healthful and greedy after food."

Of the "state of the weather" table it is well to explain that under the head of "fair" is included the half dozen or more instances in which a hazy state of the atmosphere was observed. The prevailing state of the weather is, in January fair, in February clear, in March cloudy, in May clear, in June fair, in July fair, in August cloudy, in September cloudy, in October clear, in November clear, in December clear. In 1877 the prevailing state in February, April, May, October, November and December was clear; in January, June and July it was fair; and in March, August and September it was cloudy. Snow falls most frequently in March, next in December, next in January, next in February, next in November, and least often in April. It is very rare that there is any in any of the other months. It must not be supposed that the state of the heavens is of little or no consequence so far as health is concerned. It is no exaggeration to say that the human system sympathizes with the clouds; that the pulsations of life are subject to the flitting vapors of the sky. A little floating belt of moisture may shear the withering rays of the sun of their fatal influence, or at another period of the year cut off those that are necessary to keep the vital spark alive.

It is certain that the difference in the number of hours of sunlight of the different months of the year has a great influence on the state of health and strength. The relation between life and light is intimate, as can be easily demonstrated. Thus if two similar solutions are placed, one in the light and the other not, in a short time numbers of animated creatures will soon be developed in the former, while none will appear in the latter for an indefinite length of time. It is true, however, that sunshine in large amount is entirely destructive to bacteria and other low organisms—a fact that should not be forgotten in studying the etiology of epidemic and endemic diseases. From the table of the number of hours the sun is above the horizon, it will be observed that in July there is not a very great deal less than twice as much sunlight as in December, to say nothing of its greater intensity. People who live closely in dark rooms are comparatively weak, and succumb easily to disease of any kind. Doubtless the condition of people in December, as compared with what it is in July, is somewhat similar. An excess of light, however, is perhaps injurious to many.

The excellent and still improving system of weather prediction of the United States Government, which has been in operation since 1870, should be appreciated by physicians. Guided by the daily reports, few, if any, atmospheric changes should overtake any one unprepared. I would here say that the possibility of predicting the approach of storms is by no means as recent a discovery as many imagine. In an article in the *American Journal of Science and Arts* (1871) Prof. Abbe gives the credit of it to Franklin, whom all men justly delight to honor, but any one who turns to Bacon's work, referred to above, will find that the fact was not unknown to him. Says he, "Seeing progression is always from some certain place or bound, inquire diligently, or as well as thou canst, concerning the place of the first beginning, and, as it were, the spring of any wind, * * * as, for example, if the vehement northern wind which blew at York such a day, do blow at London two days after."

(*To be Continued.*)

The HALF-YEARLY COMPENDIUM is now ready.

TREATMENT AFTER AMPUTATION, ESPECIALLY WHERE SUPPURATION OF THE FLAPS HAS OCCURRED.

BY H. L. GETZ, M.D.,
Of Marshalltown, Iowa.

In a recent case of amputation of the leg in its middle third, for a railroad injury, suppuration of the flaps occurred. I did not do the amputation, but was called to take charge of the patient about a week after the operation, when the surgeon in attendance gave it as his opinion that the patient could not recover. The entire limb, up to the hips, was enormously swollen and erysipelatous; wound gaping, and no signs of healing, but looking very unhealthy. Seeing that there was no chance for the parts to heal other than by granulation, I removed plasters and what sutures remained, to give free exit to the pus, using carbolic acid freely, as a dressing, and tonics of quinine and iron internally, in full doses, and soon had the satisfaction of finding the parts assume a more healthy appearance and the patient's bad general symptoms replaced by symptoms more favorable. But now there was something else to contend with; the anterior flap had sloughed so much that it could not be drawn over the end of the tibia, the latter projecting half an inch; it seemed now as though the bone would not be covered unless one inch or more of the bone was removed; this I would not do, on account of the patient's condition, fearing that he might relapse into the same state he was when I first saw him.

Not being able to bring the edges of the flaps together with plaster, in the usual way, and not even partially without giving the patient much pain, it now occurred to me that it would be a good plan to apply strips of adhesive plaster to each flap, extending them up the limb eight or ten inches. To these I applied cord and weights, giving the patient no pain and covering the bone more nearly than I could possibly do applying them in the usual manner. I did not even expect that I would be able to cover the bone entirely without removing at least a small segment. To my great satisfaction, however, the bone closed over entirely, and a good stump was the result; I see no other plan that could have been adopted giving such favorable results. I believe that the treatment of flaps in amputations of the extremities (where union does not take place by what is known as first intention), should invariably consist of adhesive strips and weights, instead of applying the strips as has been done formerly. The advantages are as follows:—

1. Everything is gained by strips and weights that can be accomplished in the old way.
2. Free vent is given to the pus.
3. The vitality of the flap is not interfered with by compression.
4. It is much less painful to the patient.
5. The ends of bones can be made to heal over, which could be done in no other way.

APPEARANCE OF THE TONGUE IN DISEASE.

BY J. A. HENNING, M.D.,
Of Red Key, Ind.

When a physician commences to examine a patient, generally his first request is "Let me see your tongue." The patient protrudes it a few moments, and other symptoms are examined as promptly. The doctor rarely stops to study what condition of the system is expressed by the appearance of the tongue, but only to see whether the secretions are torpid or lively. I have noticed physicians, and even professors of colleges, to thus hastily examine the tongue, and say nothing about its peculiarity or indications. When I first commenced to practice I would, as is the custom, look at the tongue, but I did not know what I could learn from it. Yet I knew very well that the peculiar appearance in different forms, and even in the same disease, with its changes, meant much more than I knew about it. Then I would look at my text books, but, as a general thing, they gave me very little light on it.

The appearance of the tongue will tell us, 1st. The condition of the digestive organs. 2d. Function of nutrition and assimilation. 3d. The nervous system. 4th. The condition of the blood. All of which we want to know from every patient before we can make, in many cases, a rational or scientific prescription.

Some of the peculiar appearances of the tongue in numerous diseases are the broad, white-coated, pallid tongue; or the deep red, sleek tongue. Then we have the pinched, shrunken, elongated, full, yellow-furred, violet, dark brown tongue, with many other varieties.

We shall not attempt to describe all the above appearances, as found in various diseases, but only call attention to the first two forms.

1. The broad, pallid, white-furred tongue, whether found in acute or chronic disease, and even in the same disease at different stages, it matters not, always indicates the want of the alkaline elements of the body. The patient that has such a tongue never wants an acid drink,

because his system is already acid whether the acid is in the stomach or blood it matters not. In such cases, with our usual prescription we must give alkalies, such as sulphate or bicarbonate of soda, in order to neutralize the acid. Then, and not till then, will our remedies act kindly and much more promptly, and the patient improve more rapidly. Now, if acids are prescribed when the tongue is broad and pallid, the system being full of acids already, it will be seen at once that no improvement could or should be expected. I remember, before I was aware of this rule, I could not see why my remedies did not improve the patient; but now I give the proper alkali, removing the acid; then the remedies act more promptly, the tongue changes to a better appearance, and the patient improves correspondingly. This acid condition of the system is probably more often found in acute than in chronic diseases; at least, that is my observation. It needs but a trial to test this principle; I have never known it to fail. I do not pretend to explain why the tongue looks thus when there is a superabundance of acid in the system.

2. The deep red, sleek tongue, with a slight coat at the base, indicates just the opposite condition; here the system is in an alkaline state, no matter in what form of disease. Then some kind of acids must be given, to neutralize the superabundance of the alkali, before other remedial agents will, or even can, have a good effect. All persons that have this peculiar tongue desire acid drinks. This tongue is often (though not always) seen in erysipelas, typhoid fever, and many other diseases, where the tr. chloride of iron or muriatic acid will be the leading remedies. But if the system was in an acid condition, known by the broad, pallid tongue, those remedies would do more harm than good. Now I do not wish to inculcate the idea that alkalies or acids will cure any disease, but the above appearances of the tongue are indicative of specific physical conditions, and those remedies are adjuvants, paving the way and assisting specific remedies.

The other peculiar appearances of the tongue above-named each have a significance, and one very important to learn; not only being a material element in making a diagnosis and prognosis, but are also indicative of treatment. Many of our best remedies fail in chronic diseases, just for the want of this simple knowledge, and this is one reason why remedies will remove the disease in one patient and fail in another, though they may have the same disease and the same remedies. Take rheumatism: sometimes an acid treatment and sometimes an alkaline treatment will cure. Failure often lies in the physician, not in the remedies. The grand secret is to know which of the two is demanded for the particular form of the disease.

The Management of Acute Catarrh of the Middle Ear.

In the Louisville *Medical News*, Dr. W. Cheatham says, on this subject: Never put a poultice over an eye or an ear. It is sometimes excusable in diseases of the former organ after all hopes of vision are gone. They give relief at first, but usually leave the organs in a much worse condition than could have been expected from the primary trouble. They lead to the growth of polypi, and get the external auditory canal into such a soggy condition as to render the case almost, if not entirely, incurable. Many of you, no doubt, have seen earaches relieved by their application, but how many of you have also seen perforated drumheads that can never be healed, recurring polypi, occlusion of external auditory canal, deformity of auricle resulting from abscesses, and many other evils which could have been avoided by the proper treatment.

I place at the head of all treatment for acute inflammation of the middle ear local blood letting. One or several leeches should be applied to the tragus, leaving them there until they are filled; then the flow of blood should be encouraged for an hour or more, the number of leeches and the length of time of the after-bleeding to be controlled by the condition and age of the patient and the severity of the case. When it is impossible to get the leeches, wet cupping over the mastoid region is desirable. Next in efficacy to local depletion comes water as warm as can be borne, by means of a douche (not a syringe), or any other arrangement by which a steady flow of it into the aching organ may be acquired. A quart or more to be used in this manner, to be repeated every half hour or hour until relief is given.

If these remedies fail, do not try anodynes yet. They only mask the symptoms. If the drumhead is bulging, perform paracentesis. The operation is a very easy one. Any one capable of seeing a drumhead should be able to do it. Under good illumination pass the knife or needle used along the floor of the canal and just posterior

to the handle of the malleus; in the infero-posterior quadrant of the membrane make your puncture. Sometimes pus will escape, other times blood or serum. After the puncture is made cause the patient to perform valsalva, or inflate with Politzer's bag and blow out any fluid which may be retained there. Where there is any doubt in your mind as to the propriety of the operation because the case is not clear to you, give the patient the benefit of the doubt. With ordinary care you cannot possibly do harm, whereas by neglect irreparable injury may be done. Holes in drumheads made by knife or needle soon heal, very often before you wish; they are usually difficult to keep open.

After free vent is given the discharge anodynes may be used. Give them for their effect and not by the dose. Quiet the pain; give rest. This subject of rest was discussed very thoroughly in the last meeting of the New York County Medical Society. Drs. Agnew, Knapp, Roosa and others agreeing on the importance of it, but not in the position of the patient during the rest. Give patient his or her choice; leave it to them entirely. Should the paracentesis close, repeat it as often as necessary. I have seen it done six or eight times in one ear with excellent result.

In all ear troubles, and especially in the one of which I am speaking, strict attention should be paid to the general condition of the patient. The skin should be kept active as far as possible, to guard against cold. An hour's cold will undo many months' treatment.

On Periodic Dipsomania.

According to Dr. J. K. Barton, in the *Practitioner*, this variety includes those patients who get periodic attacks of drinking, lasting for a long or short period. In some patients the attack comes on suddenly. That is to say, they take to drinking large quantities of alcoholic fluids without any premonitory symptom. But more often than not there is noticed an alteration in character and temper that forewarns those who have anything to do with the patient. In the case of a married man, the wife can almost always tell when an attack is coming on. The length of these attacks vary very much, more especially according to the duration of the disease in the patient. In the early history of the disease the drinking bouts often last from one to three weeks, and during that time the patient is constantly drinking. As he cannot get the quantities of liquor that he requires outside anywhere, he takes to drinking in his own rooms or house. Nothing will stop him. If his friends or servants try to get him to leave off, he storms and rages and terrifies them into submission to his ways and wants. His excuse for drinking is always that he is excessively weak and nervous and requires support, and that it is absolutely necessary for his life that he should have stimulants. His appetite soon disappears, and he only makes vain efforts to partake of any food that is brought to him. Great sleeplessness and restlessness comes on, and, in fact, the patient is often on the verge of delirium tremens when the disease abates, either gradually or suddenly, and he gets fairly well. When it ends suddenly, it is generally from an attack of acute or subacute gastritis, for which he requires and seeks for medical aid. The craving for drink having also disappeared, he willingly submits to medical direction, and under judicious treatment recovers. When the attacks go off gradually there are less severe gastric symptoms, and the craving having become less, there is a diminution in the gastric and nervous troubles.

After patients have lived for several years with these periodical attacks, the duration of attack diminishes in length, and they increase in frequency; the cause of this being chiefly due to the effects on the gastric system. The stomach much sooner resents the large quantities of alcohol put into it, and consequently the drinking fits are cut short by attacks of gastritis, and often also enteritis. But from the attack being shorter, the interval of diminution in drinking also becomes shorter, so that the patient gradually goes from bad to worse.

Tests and Preservation of Surgical Instruments.

The following directions are from a work in preparation by Dr. S. Smith:—

The *tests* of the quality of instruments are as follows: Draw a cutting instrument from heel to point slowly across the *border* of the nail, and it will catch or stop at every "nick;" draw it across the *flat* of the nail, and if at any point the edge is seen to be wiry or smooth, it is soft, and must be reapplied to the hone; but if it becomes serrated, like a fine saw, the edge is brittle, and cannot be remedied by the hone. For pointed instruments, stretch upon a test drum (a contrivance for the purpose for sale by instrument makers) a very thin piece of kid, or gold beater's skin, and push the point through. If it enter smoothly and easily the point is good; but if a slight crackling noise is heard it is defective. If a lancet is tested, see-saw the edge in the opening, and if it glides over without cutting, or cuts roughly, the edge is imperfect.

The *preservation* of instruments in good condition requires careful attention to the following details: Select a place always free from moisture and dirt, for their safe keeping. Polished instruments should be suspended or placed in velvet-lined cases. After being used, every instrument should be thoroughly cleaned with warm water, and perfectly dried with chamois, or the fire, before it is returned to the case. Silver instruments tarnish when they are exposed to the air, or are brought in contact with hard or soft rubber, caustics or acids. To preserve the edge and polish of instruments, the surgeon requires two or three small hones, some fine emery paper, two or three screw drivers, small files, rouge crocus, or other polishing powder, chamois, and gold beater's or kid skin. Cutting instruments should have their blades kept in perfect order by the judicious use of the hone. Occasionally the blade must be ground by a competent workman. Blunt instruments, which are designed to enter natural or other passages, should be frequently polished with fine emery paper, and then with rouge and chamois skin, in order to remove every particle of rust, and to maintain smooth unblemished surfaces. Saws,

are sharpened with three-cornered files, applied in the direction of the original cut of the teeth.

Surgical Operations on the Kidneys.

At the conclusion of a recital of a number of operations on the kidneys, Dr. L. S. Pilcher, in the *Proceedings* of the Medical Society of Kings County, New York, formulates the following statements:—

I submit the following propositions as abundantly proven:—

1. Incisions into the substance of a kidney are not in themselves especially dangerous.
2. The kidneys may recover from very considerable lesions, if complications can be averted.
3. Anatomically, the exposure or the removal of a kidney is not especially difficult or dangerous.
4. A single healthy kidney is capable of eliminating sufficient urine for the maintenance of health.

These four propositions being accepted, two conclusions logically follow. These I submit with a confident belief that they will in time become generally accepted as rules of surgical practice:—

I. Incisions into the substance of the kidneys for the exit of retained fluids, or solid concretions, or foreign bodies which have entered from without, or for purposes of exploration, are justifiable.

II. When a reasonable certainty exists that one kidney is healthy and the other is the seat of advanced and irremediable disease, its extirpation is justifiable.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——Dr. L. S. Oppenheimer, Demonstrator of Microscopy, Histology and Vivisection at the University of Louisville, sends a reprint containing contributions from the microscopical laboratory. There are several figures illustrating sections of diseased tissue.

——We have received several numbers of the quarterly published at Berne, Switzerland, devoted to the mechanics of medicine and surgery. It is in a new field and one that promises well. The journal is handsomely printed, with numerous illustrations.

——In some observations on amphoric respiration, reprinted from the *Southern Clinic*, Dr. M. L. James expresses his conviction that an adhesion of the pleural surface of a cavity to the chest wall is the usual condition by which amphoric respiration is produced. He has been surprised to see no mention made by the authorities of such a condition as the occasion of the production of this abnormal sound. The authorities recognize the existence of a large cavity with firm walls as the condition of amphoric respiration, but do not mention pleural adhesion as the particular circumstance by which those walls are made thus firm. Dr. James believes that this, though not the exclusive, is the usual mode.

——In an address delivered at the commencement of the seventh annual course of lectures of the Woman's Medical College, Chicago, Dr. C. W. Earle gives a history of the Institution, and states the demand for a woman's medical college in the West. This he explained to be that "the eagerness with which the initiative was taken by irregular schools and unscientific and irresponsible sects of doctors in the whole matter of woman's medical education, while it has done more than all other causes combined to bring discredit on the movement and to cause an intelligent public to distrust female physicians, at the same time evidenced the necessity of a college of this kind, and in this part of the country."

BOOK NOTICES.

Text-book of Physiology. By J. Fulton, M. D, M.R.C.S., Eng.; L.R.C.P., London; Professor of Physiology and Sanitary Science, Trinity Medical School, Toronto; Surgeon to the Toronto General Hospital, etc. Second edition, revised and enlarged, with numerous illustrations. Philadelphia, Lindsay & Blakiston. Toronto, Willing & Williamson. pp. 416. Price $4.00.

The author has aimed in this volume to present "a well-digested text-book," "chiefly intended for medical students." It contains few or no original studies, and omits references to standard authorities. The latter we consider a serious mistake in any work of the kind, as it is part of a scientific education to become familiar with the names and titles of the workers in science. The illustrations are only moderately well done, and are rather scanty in number. Occasionally no explanation is given of the figures and letters they contain. The text is accurate, so far as we have examined it, and for the purpose of giving students a clear presentation of the known and accepted physiological doctrines of the day, will answer very well. The author has made careful studies of the best and most recent works on the subject, and his style is clear and simple.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

ON THE COLLECTION OF BILLS.

With the increasing keenness in competition the ancient plan of presenting bills once a year has grown into disfavor with nearly all business men. It has been found that the more nearly we can approach a cash system the better it is for all classes; and in default of cash payment, the shorter the time understood necessary for payment, the more profitable for both parties. The popular wisdom has crystallized this truth into the antithetical proverb, that "Short accounts make long friends."

Physicians have been among the last to take note of this change. In some parts of the country it is still the custom to postpone the presentation of bills to some yearly date, Jan. 1st, April 1st, or "after harvest." Much of the financial depression of the profession is owing to this bad business habit; and lately, in this city, it has been receiving the earnest attention of one of our societies, the Northwestern Medical Association. At a late meeting, called especially to consider the financial interests of the members, the following resolution was unanimously adopted:—

"*Resolved*, That a committee be appointed to take into consideration the matter of securing the coöperation of heads of departments, presidents of railroad companies, and heads of large manufacturing establishments, in the collecting of our bills for medical attendance."

It was believed that by such action the bills due physicians by employees could be rendered more secure.

One of the members of the Committee also presented a paper to the Association discussing the general question. Some of his remarks, we believe, will be read with interest by the profession at large:—

"But what can be done? A panacea for the discomforting complications of the financial problem is, perhaps, unattainable, but remedies for their alleviation should be certainly brought within the reach of the general practitioner. The natural aversion of physicians to approaching their patrons for pecuniary aid has generally led to such postponements in presenting bills, that many have come to feel that a doctor strains a point of etiquette if he presents his bill at all, and to come twice for his money is an insult! Often physicians find it so unpleasant to repeat their calls for purposes of collection, that, after a few unsuccessful attempts with delinquents, they give it up, rather than subject themselves to the humilities of the task. This phase of the problem is a demoralizing one to the crafty and dishonest, who purposely hold back payment until the pursuit for money be abandoned, through weariness or disgust. There are errors of the public practice toward our profession that wofully need correction. One indispensable condition for their correction will be found in a cordial, steadfast union of the medical profession, or any considerable given quantity of medical influence directed toward the defence of the interests of each and all together, by an unswerving demonstration that the medical profession respects itself enough to expect and to insist on receiving a fair and reasonable pecuniary remuneration, and that, too, with considerate promptness.

"'Where there's a *will* there's a *way*'—and few indeed there be who are not as able to pay the physician as he is able to lose his earnings. By accustoming all classes of patrons to an early or earlier rendering of bills, while the amount is moderate and the service fresh in memory and appreciation, the satisfaction of both people and physician will be better assured, collections will be facilitated, friendships perpetuated, and a healthier financial morale promoted. By a protective law of human nature *carrion* is offensive to the senses, and the 'dead horse' of an old bill is always obnoxious to both physician and patron!

"If the necessary perseverance of the task of collecting be distasteful or impracticable to the practitioner, then an excellent plan is the one al-

ready adopted by this Association, viz.: the employment of a reliable, earnest, courageous, persevering collector, who can collect for a large number at the same time, and in a few months perform the disagreeable task of prompting the slow, stirring the dilatory, rousing the indifferent, pressing the dishonest and marking the 'loafers and deadheads.' While a trustworthy and accomplished collector is doing this for one, he can do it for all—thus placing every physician employing him upon a fairer and better basis for knowing exactly the financial status of his business. But single-handed effort must fail, while united effort must succeed.

"It has long been the conviction of the speaker that the adoption of a system of premiums and penalties by physicians would practically facilitate a more satisfactory adjustment of their finances. Persons who might pay more promptly often do not, for the reason that there is no practical inducement, while the tendency to indefinite postponement is encouraged, because there is no disadvantage accruing to the postponer. I believe there is propriety and practical wisdom in establishing the habit of rendering accounts for medical service at the close of each consecutive service, and that the 'terms' of the physicians be printed on the blank form of their bills; these terms to embrace the incentives to promptness by a statement of a reasonable per centum rate of interest to be charged after the expiration of a reasonable length of time, if payment be deferred. Many persons habitually in arrears might be thus encouraged to make a new start, and put themselves upon reputable record."

To accomplish the objects here proposed a uniform blank for a bill has been adopted by the Association. On its face it bears the notice—

"Bills rendered monthly, or within thirty days after service."

On one of its extremities is printed—

"Ten per cent. discount will be allowed if payment is made within thirty days."

"Lawful interest will be charged after thirty days."

On the other the name of the collector chosen by the Association is given.

By these plain notices, printed on the bill, and all the members making use of the same form, anything like personality is avoided, and no charge can be brought against any one physician that he is too eager for his pay.

If such a plan is honorably carried out in all instances, by all members, there certainly will be a gratifying change for the better in the annual balances of their books, and physicians would, if such measures were generally adopted, be relieved of many unpleasant experiences.

Notes and Comments.

Therapeutical Notes.

DISEASES OF THE SKIN.

We continue from last week our extracts of interesting formulæ from Mr. Squire's "Pharmacopœia of the British Hospital for Diseases of the Skin," beginning with some

CAUSTICS.

℞. Acidi arseniosi, gr. xx
Cinnabaris factitiæ, ʒ j
Adipis, ʒ j. M.

Used in cases of lupus. It is spread thinly on strips of linen, applied for twenty-four hours, and renewed for two or three consecutive days, if necessary, the skin being well washed after each application. Thus applied, it leaves all islets of healthy skin intact, and destroys only the lupus tissue. A chromic acid caustic used in lupus, and also for destroying warts, is—

℞. Acidi chromici,
Aquæ, āā ʒ j.

Dissolve.

This, though a strong, is not a fully saturated solution.

In lupus, and also in indolent tertiary syphilitic ulcers, the following iodine caustic is employed:—

℞. Iodinii, ʒ iij
Potassii iodidi., ʒ j
Spir. vini rectif., ʒ j. M.

A new substance for caustics, the ethylate of soda, prepared by treating absolute alcohol with metallic sodium, is used in cases of vascular and pigmentary nævus:—

℞ Sodii ethylatis, ʒ ss
Alcoholis absoluti, ʒ vj. M.

The action of this caustic may be checked promptly by dropping upon the part a drop of chloroform.

In venereal warts the savin caustic is employed, which exercises only a very superficial action—

℞. Pulveris sabinæ., ʒ vij
Zinci oxidi, ʒ j. M.

Inquiry has often been made in these pages for a depilatory. The following is given in the work before us:—

℞. Calcis sulphuratæ, ʒ iss
Zinci oxidi, ʒ vj
Carmine, gr. j M.

Mix the powder with water, to make a thin paste; allow this to remain on the skin for three minutes, and then wash it off with water.

SEAT WORMS AND PRURIGO PODICIS.

Prurigo podicis often depends on seat worms

in the rectum. The following enema is recommended "as a specific" in such cases:—

℞. Tincturæ ferri perchloridi, ♏xx
Liquoris calcis, ℥j M.

Sig.—For an enema, repeated as necessary.

When the prurigo is dependent on or complicated with a congested condition of the rectum, the following suppository is employed:—

℞. Acidi tannici, gr.xv
Pulveris opii, gr.j
Glycerinæ, ♏ij
Saponis duri, gr.viij. M.

COSMETIC POWDER.

As a sedative and cosmetic in various eruptions of the face, the following combination is employed:—

℞. Bismuthi subnitratis, ℥vj
Plumbi chromatis, gr.x
Carmini,
Cinnabaris factitiæ, āā gr.v. M.

Sig.—To be applied as needed.

Instrument of Resuscitation.

A Frenchman has the credit of inventing an apparatus for aiding in the resuscitation of persons apparently drowned, or who, from any other cause, have been temporarily deprived of animation. It consists of a cylinder of sheet iron large enough to contain the body of an adult person. It is closed at one end, and the inanimate individual is inserted, feet foremost, in the receptacle, as far as the neck, round which there is placed a padded diaphragm, fastened to the cylinder so as to be air tight. An air pump, attached to an opening in the tube, creates a partial vacuum, and then the outer atmosphere, by its own pressure, forces its way into the lungs by the mouth and nostrils, which are left exposed. By a reversed action of the pump the air is allowed to reënter the cylinder, and respiration is thereby reëstablished. A glass plate inserted in the iron casing enables the operator to watch the movements of the chest, which rises and falls as in life, with the working of the pump. The action may be repeated, it is stated, eighteen times in a minute, an exact imitation of natural breathing being thus produced.

Treatment of Ingrown Toe Nail.

Dr. James McEvoy says, in the Louisville *Medical News*, that he has found the following simple plan effective:—

A small, wedge-shaped piece of sponge tent is cut and inserted under the ingrown part of the nail, as far as possible. The size of the sponge is increased at each insertion, which is generally every third day. If there is a fetid discharge, the sponge is dipped in carbolized oil before using.

In the Chicago *Medical Journal and Examiner*, Dr. Andrews gives the following operation, as that of a chiropodist, named Willard:—

He neither extracts the nail nor slices off the overlapping flesh, but cuts out a narrow ellipse of tissue near the nail and parallel to its border, claiming that the border itself, where it rests against the edge of the nail, has its special structure adapted to its location, and ought not to be sacrificed. The removal of the strip of flesh being accomplished, he brings the edges of the wound together with fine sutures, thus drawing the border away from the nail and effecting a cure.

Massage Applied to the Eyes and the Tonsils.

Dr. H. Pagenstecher has used massage to the eyes successfully, in episkleritis, keratitis and other cases (Schmidt's *Jahrbücher*). He seizes the upper lid near the edge, and then rubs it with gentle pressure radially, from the centre of the cornea, and toward the equator bulbi.

Dr. Quinart, of Belgium, according to the London *Medical Record*, recommends, in cases of chronic hypertrophy of the tonsils, gargles of alum, combined with a massage of the tonsils, to be executed at first by the physician, later on by the patient himself. The index finger is put into some alum powder, introduced into the patient's mouth, and the gland rubbed with it in all possible directions, at first softly, later on more vigorously. After this the patient washes his mouth with an emollient gargle. In two cases the author has obtained a cure within one month, by the application of this at once mechanical and astringent treatment.

Smoking Medicines.

Smokers can now have their medicines prepared to please them, as suggested by Dr. Reginald E. Thompson, in the *Practitioner*, for April. A standard paper is formed by saturating Swedish filtering paper in a solution of nitrate of potash, with tincture of tobacco and oil of aniseed, to destroy the unpleasant odor of burnt paper. Swedish filtering paper, size 4x2½ inches; potassæ nitratis, gr.¼; tincturæ tabaci, ♏x (made with 2½ ounces of leaf to a pint of spirit); ol. anisi, ♏½. A solution of any drug desired is used to saturate the paper, and so the dose can be exactly regulated, the tobacco not causing any appreciable effect on the system. Opium was the drug used, which, in

doses of one-sixty-fourth of a grain, was found sufficient to begin with.

Naphthalin in Pertussis.

Dr. J. Pirnat, of Evansville, Indiana, writes us:—

I have, for the last sixteen months, tried the naphthalin treatment in pertussis. In my experience it surpasses all the remedies known to me for this disease. It not only relieves the patient, but it cures, in between two and four weeks. My experience extends to ten cases, three of which are still under observation.

The naphthalin in its pure state cannot be given, on account of its offensive and most unbearable smell. I prepare the liquor naphthalini, which the most delicate infant can take in sugar water, with pleasure as well as safety. I shall still further extend my trials, as well in pertussis as in other spasmodic diseases, as opportunity offers itself to me, and shall publish the result, through your journal, at some future time.

Endermic Use of Morphia by "Thimble Blistering."

This method is thus described by Dr. J. C. Watson, in the Virginia *Medical Monthly*—

An ordinary sewing thimble, a little loosely picked up raw cotton, enough aqua ammoniæ (strong) to saturate the cotton without running out, are the preliminary agents required. Gently press the thimble over the selected spot until a sensation of heat has been felt for two or three minutes; wipe away any ammonia which may remain on the surface; now, with the finger, rub away the superficial skin; apply dry morphia by at first gently rubbing on, and then carefully adding a drop of water. A small quantity of morphia may be repeated at short intervals, until your patient feels its effects or is satisfied with the relief obtained.

Malarial Diseases in Illinois.

Dr. J. W. Donnally, of Doddsville, Ill., writes us—

"The presence of malarial fever has never been so general in Central Illinois during the spring and early summer months. We had a dry winter and remarkably dry spring and summer, so far. What gives rise to the malaria? Purpura hemorrhagica is also somewhat common."

Any of our readers with recent experience in this class of diseases will do us a favor by communicating their most successful treatment.

Pyloric Incontinence.

This is a condition in which there is a continuous communication between the stomach and intestines. In order to test whether the pylorus has retained its power of contraction, the stomach is filled with carbonic acid. This is done by giving the patient a drachm and a half of tartaric acid in a little water, and a short time afterward the same quantity of bicarbonate of soda. If the pylorus be able to contract, the stomach alone is inflated, as can be easily ascertained by percussion; but if the pylorus be relaxed, the carbonic acid passes into the intestines. The latter then become tympanitic, thus rendering it impossible to trace the circumference of the stomach by percussion. In Germany Dr. Ebstein has twice had the opportunity of seeing his diagnosis of incontinence of the pylorus verified by the post-mortem examination. In both cases the patient had suffered from cancer of the pylorus; in the one, the incontinence had been complicated by stricture of the pylorus; in the other, the incontinence was owing to its destruction. He had also diagnosed incontinence of the pylorus in six other cases, five of which were probably cancers of the pylorus. Any other disease of the pylorus, *e.g.*, ulcer, would doubtless give rise to the same affection. A purely nervous cause, such as colic, gastric spasm, etc., might give rise to incontinence of the pylorus.

Prevention of Color Blindness.

M. Delbœuf has found that if a person afflicted with Daltonism looks through a layer of fuchsine in solution his infirmity disappears. A practical application of this discovery has been made by M. Javal, by interposing between two glasses a thin layer of gelatin, previously tinted with fuchsine. By regarding objects through such a medium, all the difficulties of color blindness are said to be corrected. Experiments in this city, by Dr. P. D. Keyser, affirm the success of this method.

Ice Cream and Beef Juice.

As an excellent dietary article, this is praised by Dr. J. J. Tucker, in the Chicago *Journal*. His formula is—

R.	Cream,	120 grams
	Sugar,	30 "
	Extract of vanilla,	8 "
	Beef juice,	8 "

Any confectioner can make it, or it may readily be prepared at home, with a freezer. Its uses are obvious.

Ipecac. in Dysentery.

Dr. Thomas Clarke, of Jamaica, W. I., bears strong testimony to the value of ipecac. in the dysenteries of that tropical island. In an address published in the *British Medical Journal*, he says:—

An endemic disease in which (within my own limited sphere, at any rate) I recognize a greatly improved treatment, is dysentery, both acute and chronic; ipecacuanha constituting the great basis of that success. Not that I mean to say that the use of ipeecacuanha in dysentery is anything new. It was practically known, I find, in France, so long ago as 1686; but, so far as I have ascertained, its character as a specific, or something like a specific, in dysentery, was not permanently established till within the last half-century. It appears to me to be deserving of that high character, and to have brought acute dysentery, at all events—another of the most prevalent diseases of the country—within the category of tropical diseases which are perfectly amenable to medical treatment; and to be deserving of great confidence also, if it be not an indispensable agent, in the treatment of the chronic dysentery.

How to Give Podophyllin.

This drug is especially valuable in small and continued doses, as an alterative. But it should not be given in pill form, as it acts, in that shape, irregularly and sometimes disastrously. Dr. Horace Dobell, of London, recommends the following as a most satisfactory form for its exhibition:—

℞. Podophylli, gr. ij
Essentiæ zingiberi, ʒ ij
Spir. vini. rectif. ad ʒ ij ℈ M.

Sig.—A teaspoonful in a wineglassful of water every night, or every second, third or fourth night, as required.

He has used this prescription for years "with the happiest results."

What Form of Blindness did Homer have?

Modern investigation is reinstating the blind old bard. Dr. Schliemann has proved that he sung of a real Troy and an actual war. Recent critics concede him to have been a true poet and not a myth or a mere collector, as Wolfe taught. And now another Wolfe, this time a surgeon, and of Glasgow, has published a pamphlet, in which he is pretty successful in showing that the singer of the Iliad certainly had an ocular defect, not color blindness, as Mr. Gladstone thinks, but amblyopia, from Egyptian ophthalmia. The evidence is collected from the treatment of colors in the poem.

Correspondence.

Popular Notions on the Subject of Stuttering.

Ed. Med. and Surg. Reporter:—

In some sections of this county many of the negro population, and a portion of the illiterate whites, believe if a stammerer is made to sleep with his mouth full as possible of raw beans, peas, or any similar small, round objects, it will prove a sure cure of the trouble, if persevered in every night for two or three weeks; and some well authenticated cases can be shown of persons that were once stutterers in the extreme, who, after a few weeks of said treatment no longer show much, if any, inclination to do so. And the habit is said never to return. How such an effect can by such means be accomplished is with me a question.

If stammering be the result of a disease in that portion of the brain where the so-called motor speech centres are located (and such I believe is the accepted theory), how can such treatment benefit or even tend to benefit? On the other hand, if balbuties is "owing to a born weakness of the apparatus by which syllables are coördinated," as was once supposed, could the presence of such substances in the mouth during sleep, by any stimulating effect, aid in overcoming the difficulty, or could the slight swollen condition to which they might attain by being subjected to the heat and moisture of the mouth for a few hours, benefit by dilatation or otherwise?

Should the stammering pupil be so treated each time before attempting to speak, such a device might act mentally by aiding his determination and by diminishing the anxiety to speak, thus benefiting him.

But the question is *how* or *in what way* such or similar treatment could have a beneficial effect, when instituted just prior to and during the sleeping hours, save by the possible fact that the patient knew the purpose of said treatment, and on account of it his will is strengthened, and he exerts himself to overcome his bad habit.

I hope not to be understood by the profession, or others, as recommending this as a *safe* treatment for the patient, either awake or asleep, or as ever having prescribed it.

My object in writing is twofold. First, to elicit an expression from you or some of your many readers, as to the reason of this novel, or should I say unscientific, mode of treatment. Secondly, with a hope that some of your patrons who have given this important subject and its treatment careful study may be induced to express themselves herein, for the benefit of those of us who wish to do good, but often see and feel our weakness.

J. S. Aydelott, M.D.

Snow Hill, Maryland.

[The inquiry is probably similar to that proposed by Louis xiv to the Institut—why, if a live carp is placed in a tub brimful of water, the fluid

does not overflow? The story is familiar.—Ed. Reporter.]

Suicide by Strychnia.

Ed. Med. and Surg. Reporter:—

On the 11th of June I was called to see L. D. Fletcher, who had been seized a few minutes before with convulsions. He had declined to eat breakfast that morning, and a short time afterward went to the drug store and procured three grains of strychnine, for the purpose, he alleged, of destroying rats. He immediately returned home and was seen to go to the pump with a cup in his hand, when it is supposed he took the poison. After swallowing the contents of the cup, he washed it out and returned it to its former place. Mr. F. then went into the sitting room, and after lighting his pipe, sat down on the sofa. In about fifteen or twenty minutes he fell from his seat in a convulsion. When I arrived, he was lying on the floor with eyes shut, pulse quickened, breathing a little troubled, with tremulous action of the abdomen as it rose and fell with each inspiration and expiration. He never spoke from the time he was first seized, and resisted every attempt to introduce remedies by the mouth. While I was with him he had two severe convulsions, with the last of which he had slight opisthotonos. He died while in this second convulsion, in twenty minutes after the first seizure, and about thirty-five minutes from the time he swallowed the poison.

Trappe, Md. L. Chaplain, M.D.

A Case of Substitution.

Ed. Med. and Surg. Reporter:—

On the evening of the 28th of December last we were called to attend a young lady, Kate G., who had, we learned, been the subject of a harassing cough, with profuse expectoration, for several weeks previous, but which had not until the present time occasioned the family much uneasiness. Inquiring into the history of the case, we found upon examination the upper lobe of the left lung consolidated, and rapidly breaking down, the middle studded with patches of consolidation, and the apex of the right lobe in a similar condition. The patient was weak and anæmic, but not confined to her room; diagnosed acute phthisis, and in connection with a ferruginous tonic, prescribed for the night sweats, which were very copious, the following—

℞. Dextro-quiniæ, grs. lxiv
Acid. sulph. dil., f. ℥ ij
Syrup. zingiber., f. ℥ j
Aquæ, q.s., ad f. ℥ iv. M.

Sig.—Dessertspoonful as directed.

On the evening of January 2d we saw our patient, who was much worse than previously, and said that the medicine had caused her so much nausea and vomiting that she had not only been obliged to discontinue its use, but that she had been unable since to retain anything upon her stomach, on account of the irritability produced by the medicine.

Upon asking for the medicine prescribed we were startled by its appearance. Instead of its being a dark, wine-colored solution, which it should have been if properly prepared, it was perfectly colorless, while its slight fluorescence and bitter taste bore evidence of its containing one of the cheaper alkaloids of the cinchona. A qualitative analysis showed this to be the case, and that instead of dextro-quinine, as prescribed, the sulphate of cinchona had been used as a substitute, which substitution no doubt had been the cause of the patient's suffering, besides hastening her death (for she never recovered her appetite), which occurred a few weeks later.

For the occurrence of these cases there seems but one safeguard, viz.: to send prescriptions to those druggists known as well for their commercial honesty as for their pharmaceutical ability. It is a pleasure to say that no city numbers more of these than our own. For the welfare of the profession in general, it behooves them to see that none other receive their prescriptions, since in this, as in many other cases, it is the "ounce of prevention" that is needed.

Rich. V. Mattison, M.D.

Philadelphia, July 4, 1879.

York County Medical Society.

Ed. Med. and Surg. Reporter:—

The York County Medical Society held its monthly meeting on Thursday, July 10th, at Wild Cat Falls, on the Susquehanna river, nearly opposite the town of Marietta. About thirty physicians, including those invited from Lancaster county and Harrisburg, were present. The York county doctors had their families with them, which swelled the whole number up to about seventy-five.

After a very pleasant picnic entertainment, the doctors, with their families, convened in the large hall on the grounds, and were kindly welcomed and thanked for their attendance, by Dr. T. M. Lochman, President of the York County Society, which was happily responded to by Dr. H. L. Orth, of Harrisburg. The regular order of business of the Society was dispensed with, and the Secretary, Dr. S. J. Rouse, announced that Dr. W. S. Roland had been requested to prepare an essay for the occasion, whereupon the Doctor read a paper on "Our Profession Then and Now," which was received as the property of the Society and a vote of thanks tendered him.

The Executive Committee of McCall's Ferry Medical Association met at the same place, to make arrangements for their annual meeting, and it was decided to hold the next meeting at McCall's Ferry, on Thursday, August 28th, and to invite the families and friends of the members.

McCall's Ferry is on the Susquehanna river, reached by railroad running from Columbia to Port Deposit. The road is picturesque all the way down.

The Association at present comprises the medical societies of Lancaster, York, Dauphin and Cumberland counties, and I learn that it is the intention of the Committee to invite other societies and physicians to the meeting. I favor,

not only county societies having their meetings in different localities in the county, but most strongly an annual union or reunion meeting of several adjoining county societies, for these meetings must tend to foster friendship, elevate dignity, and advance the standard of professional interests. R.

York, July 14th, 1879.

A Simple Cure for Ulcer of the Rectum.

ED. MED. AND SURG. REPORTER:—

I have been subject to piles for about five years; they troubling me more especially through the busy season of the year (viz., the summer and autumn months).

Last season, with the return of summer sickness, my piles returned also, in an aggravated form.

About one-half the territory of my practice is so broken that I am compelled to travel on horseback. This source of irritation prevented a successful therapeutical application; consequently, the tumor soon disgorged itself, and hemorrhage more or less followed for two or three months, gradually ceasing, and instead, a purulent discharge took its place, annoying me very much by its filthiness, and the thought that the ulcer would terminate in a fistula.

I used various local applications, as lead, zinc, sal. sol. of tannin in glycerine, cold water, etc., but with only temporary benefit. About two months ago I commenced the practice of bathing my fundament in cold water immediately after defecation, thoroughly cleansing the rectum to a point above the ulcer, and then stuffing the rectum in the vicinity of the ulcer with dry tannin.

I followed this treatment regularly for two weeks, at which time I found the discharge had ceased and all unpleasant sensations were gone. Up to this period I have had no return of discharge or any symptoms of the presence of the ulcer, notwithstanding I am riding from ten to twenty miles a day. J. J. FLY, M.D.

Pulley's Mill, Ill., July 18th, 1879.

Scrofulous Abscess.

ED. MED. AND SURG. REPORTER:—

A few years ago a lady relative of the writer had been for a long time very much annoyed by a constantly recurring abscess of the so-called scrofulous nature, situated always in the glands of the left axilla. So frequently did these "gatherings" occur that, at times, scarcely had one healed up ere there were premonitions of its successor. The usual remedial agents were one after another used, either without the slightest avail or with a merely palliative effect. Finally, the following combination was given to her:—

℞ Syr. rumicis crispi,
Ext. stillingiæ, fl
Ext. sarsaparillæ, fl āā

A teaspoonful was given three or four times per day, with singularly marked success as the result. The murmuring intimations of an incipient abscess were promptly quelled, and from that day to this, by an occasional resuming of the medicine, she has altogether avoided a recurrence of the abscess. Since that time I have had occasion to use the same preparation in similar cases, and always with the same gratifying effect. Though prescribed in the case first mentioned by other than a regular physician, it certainly deserves consideration and trial at the hands of the profession. As to the efficiency of the combination, I am satisfied, as to the active agent or agents entering into the formula, there may be a question. The alterative power of stillingia sylvatica cannot be mooted; it is one of the most valuable of its group. Rumex crispus, though ignored by many of our writers on materia medica, is not inferior in this respect to stillingia. I am sure of its depurating power, from trial and observation. As to the value of sarsaparilla, I think the profession must agree with Bartholow, who says, "It is extremely questionable whether sarsaparilla has any therapeutic power." J. W. HICKMAN, M.D.

"Tartar Emetic in Rigidity of the Os Uteri."

ED. MED. AND SURG. REPORTER:—

In the number of the MEDICAL AND SURGICAL REPORTER for July 12th, I find, reported by Dr. J. A. Irvine, an illustrative case of the efficacy of tartar emetic in rigidity of the os uteri. Like Dr. Irvine, I also was a quondam pupil of the late Dr. Hall, of Montreal, therefore, I hope it may not seem presumptious in me to offer further testimony in favor of the use of tartar emetic in this complication of labor. By referring to my obstetrical records, I find there reported 218 cases of labor. Of this number 167 were complicated with rigidity of the os, in which tartar emetic was given in small and repeated doses, with astonishing good effects. My mode of administering it is to dissolve one grain in twelve teaspoonfuls of water, of which solution a teaspoonful is to be given every fifteen minutes, until the os is fully dilatable.

One fault I find with most general practitioners (non-obstetricians), is that they will give ergot in all cases of labor indiscriminately, without any regard to the condition of the os, and in cases where there is rigidity I am fully convinced that this mode of practice tends more to retard the progress of labor than to accelerate it.

A. O. SIMPSON, M.D.

Thompson, Pa., July 17th, 1879.

NEWS AND MISCELLANY.

Items.

—*Correction.*—In the formula quoted from Dr. W. F. Hines, on page 57 of this volume, the amount of water and syrup should be of each ℥ ss instead of ʒ ss.

—The Indianapolis *News* says: The Government has contracted for 8000 bottles of carbolic acid, to be used as a disinfectant in the army The acid is to be put up in Jeffersonville.

Personal.

—M. Koeberle, of Strasburg, has, during the last four years, performed 100 ovariotomies, with 89 recoveries and 11 deaths. In 1878 he performed 4 gastrotomies, only one of which proved fatal.

—In the organization of a permanent Board of Health, under the Tennessee State Act, at Knoxville, Tennessee, last month, Dr. A. B. Tadlock, who has been a contributor to the columns of the REPORTER for several years, was chosen President, and Dr. J. P. Park, Secretary.

—Dr. Laurence Turnbull, of this city, has sailed, to attend the British Medical Association, which meets at Cork, August 5th. He has been invited by the President and Committee of Reception of the Association to read a paper on "Tinnitus Aurium," and open the discussion before the Sub-Section on Otology. Dr. Sayre, of New York, opens the discussion on his plaster jacket, and Professor Barnard delivers the opening address on Surgery.

—The charges against Dr. William A. Hammond and others, who insisted on an investigation of the management of the New York Insane Asylums, diligently circulated by the Albany *Argus*, the Buffalo *Medical Journal*, the St. Louis *Medical and Surgical Journal*, etc., have been denied and refuted by Dr. Hammond; and from a careful perusal of the statements published by each side, we are of opinion that Dr. Hammond is right in this controversy, and that Dr. Gray, of Utica, his principal opponent, has placed himself in an unworthy position.

American Ophthalmological Society.

This Society held its regular session this year at Newport, R. I., commencing July 24th. The following officers were elected for the ensuing year: President, H. D. Noyes, of New York; Vice President, W. F. Norris, of Philadelphia; Secretary and Treasurer, Dr. R. H. Derby, of Boston; Corresponding Secretary, J. S. Pronte, of Brookline; Publication Commissioners, E. G. Loring and D. B. St. John Roosa, both of New York. It was voted to hold the next annual meeting in Newport.

The Quinine Trick.

Just as we predicted, and as it required no extraordinary insight to foretell, no sooner was the duty taken off quinine than the price in London has risen from one to two shillings an ounce, with a corresponding rise in this country. Why? Because Congress, while taking the duty off quinine, left it on cinchona bark, and also left the heavy taxes on the alcohol and solvents, which the American manufacturers have to pay and the foreigners do not, and thus virtually drove the former out of the business of making the alkaloid, and threw the whole control of it in the hands of foreign manufacturers and drug brokers. These can now make us pay pretty much what they please, and we need not expect, and don't deserve, mercy at their hands. This is the result of the policy of secret dealing and political wire pulling which we referred to on page 61 of this volume; this is the fruit of an avoidance of a fair and open discussion of the question before taking action upon it.

Vaccination Items.

—The vaccine physicians of the Board of Health of this city have vaccinated nearly six thousand children in the city and suburbs this year. Nearly five thousand have been vaccinated since the 1st of April. The physicians are paid forty cents for each city case, and seventy-five cents for each case in the rural districts.

—The French Society of Hygiene, in Paris, has just opened an establishment where vaccination is carried on gratis. Lymph, both from the infant and from the heifer, is always kept on hand, and delivered to any one upon application.

QUERIES AND REPLIES.

Dr. J. W. C., of Ala. 1. Is the general opinion of the profession in favor of iced drinks *ad lib.*, in measles and similar febrile complaints? 2. Can the febrile symptoms be relieved by any other means than by opiates, diaphoretics and refrigerant drinks?

ANS. 1. We believe it is. 2. Baths, affusions, cool air and specific antipyretics may be suggested.

Dr. J. N. P., of Iowa. Will you, or some reader of the MEDICAL AND SURGICAL REPORTER, give me the best receipt to apply to the *red surface* after psoriasis has been cured?

ANS.—The redness is owing to enlarged capillaries; painting the part with collodion, or with styptic collodion, would probably contract them. A solution of solid extract of ergot has also been used locally in such cases.

Dr. F. P., of Mo. Vertigo arises from so many causes that we can make no suggestions in your case. Dr. Ramskell, who writes on it in Reynolds' *System of Medicine*, treats it, if from gastric causes, with alkaline purges, followed by a course of strychnia; 'essential vertigo' he finds most benefited by iron and strychnia, alternated with tincture of larch and digitalis. He attributes, in fact, the former to weakness of the stomach, and the latter to atrophy of the heart.

State Med. Yes, in Malta, both medicine and medical attendance are furnished free by the Government, to all the inhabitants, civil and military, rich and poor. For all that, many prefer to pay their own doctor and buy their own medicines.

Senex. An article on the subject will be published shortly.

MARRIAGES.

IRWIN—MATHER.—May 28th, at the M. E. parsonage, Fostoria, Central Ohio Conference, by Rev. D. D. Mather, pastor, Joseph W. Irwin, M.D., of Evansville, Ind., and Miss Stella Idalette Mather, daughter of the officiating minister.

PATTERSON—WHITNEY.—In Lowell, May 20th, by the Rev. G. L. Westgate, assisted by Rev. C. D. Barrows, of the Kirk Street Congregational Church, David N. Patterson, M.D., and Miss Adeline S. Whitney, younger daughter of George T. Whitney, Esq., all of Lowell.

SCHAUS—JOHNSON.—On Tuesday, June 17th, at the residence of the bride's parents, St. Louis, Mo., Hermann Schaus, of New York, and Emilie Desruisseaux Johnson, eldest daughter of Dr. I. B. Johnson.

DOCTOR RABUTEAU'S

(Laureate of the Institute of France.)

DRAGEES, ELIXIR & SYRUP

Of Proto-Chloride of Iron.

"The experiments made in the hospitals of Paris have demonstrated that *Dr. Rabuteau's Dragees, Elixir and Syrup* regenerate the red globules of the blood with a rapidity never observed with the use of the other ferruginous preparations. These results have been proved by the various *Compt-Globules.*

"The ferruginous preparations of *Dr. Rabuteau* do not cause any constipation, and are perfectly tolerated by the weakest persons."—*Gazette des Hospitaux.*

Dr. Rabuteau's Elixir is prescribed when some difficulty is experienced in swallowing the Dragees; it is especially adapted to weak persons, whose digestive functions need strengthening or stimulating.

Dr. Rabuteau's Syrup is especially prepared for children, who take it readily, because of its agreeable taste.

MEYNET'S

DRAGEES OF COD-LIVER EXTRACT.

Careful experiments have established the fact that the **EXTRACT OF COD LIVERS** contains very valuable properties, which render it superior to the ordinary cod-liver oil. It is composed principally of *Gaduine*, large proportions of *Iodides, Chlorides, Bromides, Phosphoric Acid, Lime, Soda* and *Ammonia*, and especially *Propylamin*, all of which enter, but in very small proportions, into cod-liver oil.

These dragees of pure cod-liver extract take the place of cod-liver oil, and have been used with eminent success by medical celebrities of Europe in cases of *Scrofula, Rheumatic Affections, Rachitism, Phthisis*, and in all cases where a propylamic medication is indicated.

MEYNET'S DRAGEES are sold in bottles containing 100 dragees. Dose, 2 to 6 a day. Each dragee is equivalent to two tablespoonfuls of cod-liver oil.

MEYNET'S GRAINS are small granules intended for children. 10 are equivalent to 1 dragee.

E. FOUGERA & CO., New York, Agents for the U. S.

RIGOLLOT'S MUSTARD PAPER.

Is one of the most important and useful discoveries of the age, but it is not (as certain dealers of bad faith pretend) a preparation that any one can make, for it is not manufactured with a mustard that every one can buy.

RIGOLLOT'S MUSTARD PAPER.

Is the invention of Mr. P. RIGOLLOT, who is the exclusive owner; it is the only preparation which has been adopted by the civil and military hospitals and the armies and navies of France and England, and which has obtained a medal at the Centennial Exposition at Philadelphia. All other mustard plasters or leaves of whatever name, are but imitations of the original

RIGOLLOT'S MUSTARD PAPER.

Physicians will find it the most reliable sinapism, prompt and certain in its action, and will therefore always prescribe it. Every sheet in order to be genuine must bear the annexed signature of the inventor, P. Rigollot

Sold in tin boxes containing 10 sheets, also 25 and 100 sheets, by all respectable chemists throughout the world.

E. FOUGERA & CO., Agents,

NEW YORK.

PHOSPHOROLE.

PHOSPHORUS and COD-LIVER OIL

have now an established position throughout the civilized world as important therapeutical agents. A *perfect combination* of the two has long been a desideratum, since they are both of value in the same disorders, while the cases in which one is demanded and the other contra-indicated are exceedingly rare.

The combination in PHOSPHOROLE has the twofold advantage of furnishing *the best possible form* for the administration of *phosphorus*, and *a more effective form* for the administration of *cod-liver oil.*

With regard to the former, it has been decided by the highest chemical and medical authorities that *phosphorus* should be administered *in a free state*, and in a vehicle which ensures its *perfect diffusion*, its *absolute unalterability*, and, as far as possible, its *prompt assimilation* without the gastric irritation to which the ordinary methods of exhibiting the agent give rise. It is well known that pills, emulsions, solutions in ether, chloroform, vegetable oils and resin, etc., have all failed to fulfill one or more of these conditions. Even an ordinary solution of phosphorus in cod-liver oil would not answer the purpose in all respects. We claim, however, that PHOSPHOROLE completely satisfies all the conditions. From the method of preparing it, in an atmosphere of dry carbonic acid, the phosphorus is *entirely dissolved without oxidation*, and by our mode of manipulation *a positive uniformity of strength* is ensured. It is then promptly bottled and sealed, and its *stability and permanence* thus secured. The exact amount of phosphorus in each dose is known, its efficiency is ensured, and the irritant effects upon the stomach are reduced to a minimum by the blandness of the oil. As a means then of administering *phosphorus* in the many cases in which it is indicated as a *nervous tonic and stimulant*, it is claimed that PHOSPHOROLE is the best attainable in the present state of our knowledge.

The value of *cod-liver oil* in phthisis is so familiar to the physician that it is needless to dwell upon it. But the value of *phosphorus* is also universally recognized in this disease, especially when complicated with nervous derangements. The *combination* of the two therefore furnishes a more effective form for the administration of cod-liver oil in the great majority of cases in which that remedy is indicated, and one which will at once commend itself to the profession.

A dose of two teaspoonfuls of PHOSPHOROLE contains $\frac{1}{100}$ of a grain of phosphorus. This dose, when given after a meal, is effective, and not very liable to interfere with digestion. *Phosphorus is cumulative in its action, and should be administered with watchful care.* About $\frac{1}{12}$ grain is considered the largest safe dose, and we rarely need go higher than $\frac{1}{20}$ or $\frac{1}{80}$ of a grain. At the very first appearance of the smallest gastric derangement, the exhibition of phosphorus should be stopped.

PHOSPHOROLE is handsomely put up in pint bottles only, and may be obtained at all first-class druggists throughout the United States.

Descriptive Circulars furnished upon application.

WYETH'S
DIALYSED IRON.

(FERRUM DIALYSATUM.)

A Pure Neutral Solution of Peroxide of Iron in the Colloid Form. The Result of Endosmosis and Diffusion with Distilled Water.

PREPARED SOLELY BY

JOHN WYETH & BRO.,

PHILADELPHIA.

This article possesses great advantages over every other ferruginous preparation heretofore introduced, as it is a solution of iron in as nearly as possible the form in which it exists in the blood. It is a preparation of invariable strength and purity, obtained by a process of dialysation, the iron being separated from its combinations by endosmosis, according to the law of diffusion of liquids. It has no styptic taste, does not blacken the teeth, disturb the stomach, or constipate the bowels.

It affords, therefore, the *very best* mode of administering

IRON

in cases where the use of this remedy is indicated.

The advantages claimed for this form of Iron are due to the absence of free acid, which is dependent upon the perfect dialysation of the solution. The samples of German, French and American Liquor Ferri Oxidi Dialys. which we have examined give acid reaction to test paper. If the dialysation is continued sufficiently long, it should be tasteless and neutral.

Our dialysed Iron is not a saline compound, and is easily distinguished from Salts of Iron, by not giving rise to a blood-red color on the addition of an Alkaline Sulpho-Cyanide, or a blue precipitate with Ferro-Cyanide of Potassium. It does not become cloudy when boiled. When agitated with one part of Alcohol and two parts of Ether (fortior), the Ether layer is not made yellow.

Physicians and Apothecaries will appreciate how important is the fact that, as an antidote for Poisoning by Arsenic, Dialysed Iron is quite as efficient as the Hydrated Sesquioxide (hitherto the best remedy known in such cases), and has the great advantage of being always ready for immediate use. It will now doubtless be found in every drug store, to supply such an emergency.

Full directions accompany each bottle.

Physicians will find our DIALYSED IRON in all the leading drug stores in the United States and Canada.

It is put up in bottles retailing for **ONE DOLLAR**, containing sufficient for four months' treatment Large size is intended for hospitals and dispensing. Retail at $1.50. Price Lists, etc., sent on application.

OFFICINAL ALCOHOL AS A STIMULANT.

BY D. C. LEAVENWORTH, M.D.,
Of New Haven, Conn.

My attention was called to this subject, and much interest awakened in my mind, by a conversation held some time since with an eminent physician of this State, in which, speaking of the indiscriminate prescribing of brandy, whisky, etc., he said, "it would be more judicious and safer to prescribe diluted alcohol, instead of the various concoctions purporting to contain alcohol; as then we should have more certain knowledge of what we were doing." There is no doubt that he was right in this opinion, and his words have often occurred to me since, as I reflect on the comparative certainty we have of the purity and strength of officinal alcohol over the mixtures which we know in many cases are not pure or reliable.

When we take into consideration the physiological and therapeutical effects of alcoholic stimulants on the human system, and the custom that generally prevails among physicians of prescribing these stimulants in some form for various diseases, I think it is evident, and will be admitted by most of us, that the subject is worthy of careful thought and attention by the profession. And taking another aspect of the question, it behooves us to exercise a wise discretion, on account of the idiosyncracies of our patients, in order that a craving for stimulants may not be fostered or engendered, thus causing evil results in their future lives. Our course in this respect is closely observed, especially in these days, when so much effort is being put forth to save those who are addicted to, or easily tempted to, the excessive use of intoxicating liquors.

In this paper I shall endeavor to indicate to members of the profession that by prescribing officinal alcohol properly diluted, we can meet the various necessities of our patients in a better, safer, and more certain way than the present form of prescribing alcoholic stimulants in the form of brandy, whisky, etc. Dr. Lucas, in a communication to the London *Medical Times*, says: "The advantages are great of prescribing properly diluted alcohol instead of brandy, etc., thus avoiding the evils and uncertainty attending the mode of administering alcoholic stimulants in the usual form." I think it will be admitted by most medical men that in whatever form we prescribe alcoholic stimulants for disease, the main purpose is to introduce into the system, for its therapeutical effect, a definite amount of alcohol which these articles are supposed to contain. Alcohol, as we are aware, is a word of Arabic origin, and is at the present time used to designate the spirituous element of fermented liquors. Chemists describe absolute or anhydrous alcohol as a colorless volatile fluid, of a peculiar odor and pungent taste. It boils at 172°, and has never been frozen, although Faraday succeeded in thickening by a cold of 166° below zero. It unites with water in all proportions, heat being evolved, showing a chemical union. Its formula is $C_4 H_6 O_2$.

Now I presume that most physicians will concede that alcoholic stimulants should be prescribed with as much care and caution, in cases of disease, as other medicines; at least, we should ex-

ercise as much caution in prescribing them; although I am inclined to think that many times we are incautious, apparently regarding their therapeutical action of less importance than other remedies we are using, whereas they may be the most potent medicine we are using in the case. It is also of the utmost importance to know the amount of alcohol in the stimulants we are prescribing; therefore, in whatever form we order their use, they should be of known strength and purity. There is no reasonable doubt that alcohol, sold and dispensed under that name by the apothecary, is of a definite strength and purity, as by repeated distillations it has been deprived of fusil oil and other impurities. I believe it is exceedingly rare to find it adulterated; at least, its strength and purity can comparatively be easily and readily ascertained, thus affording us an article that we can prescribe with confidence. Now we all know the case is far different in regard to the so-called gin, brandy, whisky, etc., that we are usually prescribing. The quantity of alcohol in these stimulants varies, depending to a great extent upon the character and honesty of those who deal in them. Nor can we as readily or easily test their strength and purity, as the process of analyzing them is comparatively complicated, on account of the variety of ingredients mixed to flavor, adulterate and cheapen them. Therefore, being aware of the difficulty of obtaining them free from adulteration or of proper strength, I take it for granted that many physicians, when prescribing alcoholic stimulants in the usual form for critical diseases, experience much anxiety in regard to their effect on the patient, knowing the result of our treatment will to a great extent be influenced by the quality of the stimulant used. Yet in many, if not in most cases, we know it is doubtful if brandy, whisky, etc., free from adulteration and of reliable strength is procured. I am persuaded that this proposition of prescribing diluted alcohol instead of the usual stimulants we have so long been in the habit of prescribing, will take many physicians by surprise, and objections will readily occur to them, some of which I will briefly consider.

It is thought the taste and odor of diluted alcohol will be repugnant and unpleasant to patients; but this could be obviated by flavoring it with some extract, essence, or aromatic tincture, or combining it with other medicine we are administering at the time, and thus it could be prescribed more definitely as a medicine, which would prove advantageous in many respects.

Again, it is claimed there are certain medicinal properties in brandy or gin, which alcohol does not contain, for instance, the diuretic effect obtained from gin, and the astringent property of brandy. But in respect to this, I think we could compound with the alcohol a diuretic or astringent which would prove more beneficial, besides being more appropriate to the particular disease we are treating. The stimulant effect of whisky or brandy is asserted by many to be more speedy and decided, but careful observers inform us that the stimulant effect of diluted alcohol is more certain and speedy.

Dr. Lucas, whom I have before quoted, says, "The stimulating effect of diluted alcohol, when desired, seemed to be more marked and rapid, and more lasting, than when an equivalent of pure brandy was allowed." He says further, "If we watch the patient after he has taken three drachms of alcohol, an amount equivalent to six drachms of brandy, we notice almost immediately the pulse becomes fuller and stronger, and the limbs, which may have been previously cold, become warmer." Other observers also testify to the more beneficial and comparatively more rapid effect of alcohol. Patients declare that the effect is felt immediately, and it revives them at once.

In fact, most of the objections against prescribing alcohol properly diluted, instead of the uncertain and in many cases adulterated mixtures we have, in a measure, from custom and habit, been compelled to use so long, vanish, after thorough investigation. I feel assured that if we substituted one for the other, as I have suggested, besides being gratified and pleased at the results that will follow, we shall also be surprised, as we have been in the past over other medical changes. There are many advantages in the substitution, among which the one I have urged, viz., the definite knowledge of the amount of absolute alcohol in the stimulant we prescribe. I refer to this again because it is of the utmost importance, and it is surprising that physicians have so long been satisfied to prescribe stimulants in the usual form when we realize the indefinite knowledge of their alcoholic strength, and what necessarily follows, the uncertain effect they have in disease. Another great advantage is that it enables us more readily to adapt our stimulant to the variety of disease we are prescribing for, more particularly to each case, especially in combining medicinal agents with the stimulant at the right time.

Again, the reduced expense is of much consequence. We know there are enormous profits realized from the manufacture and sale of

spirituous liquors—profits much enhanced by adulteration. All this cost entails a great burden on the poor; and, in fact, a burden in some degree on all who are compelled to purchase them for the sick and invalid. It also involves more expense in sustaining our hospitals. It is well known that during the late war the cost of furnishing our army and navy hospitals with medicinal liquors was very great; an expense entirely disproportionate to the actual amount required or used for the wounded or sick. It was admitted to be a source of demoralization to many of the surgeons, officers, hospital attendants and nurses.

Now this would be obviated to a great extent by adopting the use of pure alcohol, excluding other alcoholic stimulants and compounds under their various names. In the case of army and navy hospitals, the comparatively compact form in which it could be kept and stored would in a considerable degree lessen the expense of transportation, which is quite a consideration, especially in regard to army hospitals, which in time of war are often moved from place to place, besides taking from them a prolific source of temptation and evil.

Finally we can, to a great extent, obviate the evils which we are accused of bringing on the community, by causing the excessive use of, and inducing a taste for, intoxicating liquors by indiscriminately prescribing the various alcoholic stimulants in the form of wine, brandy, whisky, etc. Now by substituting pure alcohol, and prescribing it in the manner and under the form of medicine which I have suggested, and judiciously framing our directions to nurses and attendants, I am persuaded that we can, to a considerable extent, prevent excess and a continuance in their use after the sickness is past. Every medical practitioner has a great responsibility resting upon him in regard to this question, and can, by exercising wise care and thought, exert much influence toward preventing the excessive use of intoxicating beverages which cause so much evil in the country.

The German Society of Public Health

(*Verein für öffentliche Gesundheitspflege*) will meet in September next, at Stuttgart, from the 15th to the 17th. The subjects for discussion are, 1. Methods of Disinfection. 2. Measures for Preventing the Introduction of Contagious Diseases from Foreign Countries. 3. The Hygienic Requirements of Boarding and Lodging Houses. 4. The Necessity of Erecting Public Mortuaries. 5. The Management of Public Bathing Establishments.

THE RELATION OF AGE AND THE SEASONAL DEATH RATE.

BY T. S. SOZINSKEY, M.D., PH.D.,
Of Philadelphia.

(*Concluded from page* 98.)

The following tables give the number of deaths, exclusive of premature births and stillbirths, for each month, in full, of the year, for the three years on the average, at the ages specified; also for the year 1877 :—

	under 1	1-2	2-5	5-10	10-15	15-20	20-30	30-40	40-50	50-60	60-70	70-80	80-90	90-100	over 100
January	258.3	99.6	160.0	76.6	20.6	41.0	137.6	143.3	115.0	109.6	102.3	102.0	54.0	7.3	0.6

The statistics given, in my article referred to above, show how the mortality, in the aggregate, varies with the season of the year. The task of showing the causes at work to produce this variation in the mortality, as well as the ages at which it has occurred, is a far more difficult one, one which it is, perhaps, impossible to satisfactorily

master. There is so much room for improvement in our knowledge of meteorology, and the physiological and pathological effects on the system of its constituent elements, that it is rash to even attempt this undertaking. The writers on this subject are usually satisfied to trace a connection between the mortality and one element of meteorology, namely, temperature; but it must be clear to the appreciative reader of what precedes that any such effort is entirely unscientific. It is the duty of the physician to take into consideration the influence of each of the manifold atmospheric agents in operation in explaining the morbid phenomena which come under his observation. In an elaborate and, in some respects, a well-considered article on the relation of moisture in the air to health and comfort, by a noted civil engineer of this city, published in the *Journal of the Franklin Institute* last year, and widely copied, the following constitutes the main conclusion of the discussion: "The difficulty of absence of moisture in air that is heated in winter is a matter to be disposed of with some happiness by asserting it is not wanted." In the same article it is questioned whether electricity has any effect on the system, and it is declared that carbonic acid may be breathed with impunity. While the public ear is open to receive such stuff as this it cannot be expected that meteorology will receive serious attention from many.

The relation of the meteorology to the mortality in England has been carefully studied by Dr. Edward Smith. In his book, "Health and Disease" (1864), he has drawn the conclusion that "the foundation of seasonal disease is the varying degree of vital action proceeding within the body at the different seasons of the year;" and goes on to say that "the human system varies in its amount of vital action in a very definite manner, the maximum being in spring, the decline and the minimum in the summer, the minimum and the increase in the autumn, and a stationary elevation in the winter. Just in the like order is it exposed to the exaggerations of these tendencies. * * * As a rule, the diseases of the end of autumn are those of exhaustion, while those of winter and spring are known as inflammations, and those of autumn and the end of spring are marked by such conditions as result from rapid variation in the animal economy in its relations to the influence of external agents." I give these statements as interesting, but I believe they are only generally speaking true. They do not hold good equally well at every period of life, and in all persons alike at any particular age. The subject is interesting, but it cannot be dwelt upon now. In an article in the *American Journal of Medical Sciences*, April, 1877, on the relation of weather changes to neuralgia, Dr. Weir Mitchell makes the assertion that spring "is, in America, the season of greatest depression of health tone." This statement, like others in the same article, is much too sweeping and indefinite. America is such an extensive country that its climate in different parts is as opposite almost as the Poles, and the effects of spring weather are very unlike in persons of different age and constitution, but it is true that more adults, at least, die in spring in Philadelphia than in any of the other seasons.

It appears that in Philadelphia the months of least and of greatest mortality among persons under one year of age are November and July, respectively; among persons from one to two, October and July; among persons two to five, September and March; among persons five to ten, August and January (May the same); among persons from ten to fifteen, October and July; among persons from fifteen to twenty, June and August; among persons from twenty to thirty, and each succeeding decade up to sixty, September and March; among persons from sixty to seventy, September and April; among persons from seventy to eighty, September and March; among persons from eighty to ninety, June and March; among persons from ninety to one hundred, August and March; and among persons over one hundred, September (October and November the same) and December. It may perhaps be stated that in adult life September is the least fatal month, and March the most. The special characteristics of these months should be carefully studied. March is not, in temperature, barometric pressure and amount of light, an extreme month, but it is such in miles of wind, and almost such in range of temperature, and is markedly variable in pressure, degree of relative humidity, direction of the wind and state of the weather. It is a transition month, and it is the one in which inflammatory diseases are most prevalent. September is the contrast of it in nearly every respect.

From the table of mortality in 1877 it appears that the months of least and of greatest mortality among persons under one year were November and July, respectively; among persons from one to two, February and July; among persons two to five, February and December; among persons five to ten, April and December; among persons ten to fifteen, January and April; among persons fifteen to twenty, June and April;

among persons twenty to thirty, September and April; among persons thirty to forty, November and March; among persons forty to fifty, and from fifty to sixty, September and April; among persons sixty to seventy, September and May; among persons seventy to eighty, October and March; among persons eighty to ninety, November and April; and among persons ninety to one hundred, September and December. I need not go into an explanation of the difference between these points in the mortality of the average of the three years and of 1877 alone, as it will be included in what follows. In this connection, the following paragraph, from the work of Celsus quoted from above—the only important medical work bequeathed to us by the Romans—will doubtless be read with some interest: "As to the different ages, children and those a little advanced have their health best in the spring, and are most safe in the beginning of summer; old men in the summer and the beginning of autumn; the young and middle aged in winter. Winter is more hurtful to old men, and the summer to youths."

In beginning my systematic analysis of the tables with the list of deaths of persons under one year for each month of the year, it is proper to observe that the number of children born is not the same month after month. The figures for a series of years show that about fourteen per cent. less births occur in Philadelphia in April than in January. April, May, June, February, March and November are the months in which the deficiency is specially noticeable. The most marked feature of the infantile mortality is its excess in the heat of summer—it is over four times more in July than in November. From the falling off in the number of deaths in the autumn months an increase begins in December, which augments until toward the end of March, when a slight decrease is observable, which lasts until near the end of May, the time in which the great summer fatality begins. It is more than probable that the autumn months present a better showing than they deserve; for the reason that the very trying influence of the two months which precede has cut off most of the feeble children. Moreover, the whole number of children under one year of age is then, especially in November, less, I believe, than at any other period of the year. Perhaps, on the whole, the spring months are the most favorable to the infant population.

Now, looking down the column of the mortality among children under one year of age, for 1877, it will be observed that it corresponds in the main with that of the average for the three years. April and December are the only months in which the number is greater; in all the others, and markedly so in January and July, it is less. What meteorological reasons can be given for these points of difference? The unusually heavy mortality in April, 1877, may be accounted for by an unusually high mean and high range of temperature, high relative humidity, low mean and great range of pressure, much easterly and high winds and many rains. Turning to December, it is observed to have been a month in which the temperature and pressure were unseasonably high, with slight range of either, much wind from the northeast and south, and little rainy and much clear weather. The deficiency in January is accounted for by a low mean temperature of but slight range, low mean pressure with great range, high relative humidity and much westerly wind. July's deficiency may be attributed to high relative humidity, little southerly wind and many rains. The reader may profitably make a similar analysis for each of the remaining months. It would seem that very warm, dry air is extremely fatal to infants, and that the reverse is true of moist, cool air.

The bulk of the mortality of children between one and two years of age occurs in the warm months. The mortality in July is nearly three times what it is in October. The effects of the warm season are almost as manifest here as with younger children—the relative number of deaths being almost as great. All the months except May and December, in 1877, were a little less destructive to life at this age than usual. As a whole the year was slightly milder than the average; but it will be worth while for the reader to look over the meteorology of each month. May and December were dryer and clearer than usual, with greater range of barometer and thermometer.

Between the ages of two and five the month of greatest mortality is January; cold now, and not heat, which has so marked an effect up to this period, is most fatal. The fatal influence of heat, however, is still apparent. During this period, and in every succeeding one, there is a notable October increase in the death rate. March and December are the only months of 1877 in which the mortality is above the average for the three years; in all the others it is less, just as at the last period.

Between five and ten the effect of heat is imperceptible; but the reverse is true of cold. Least deaths occur in August, and most in January (same in June). Few of the diseases which are fatal at this period of life prevail to any

great extent during the heat of summer; scarlet fever, diphtheria, measles, etc., prevail most in the colder months. All the months except December, of 1877, are below the average in mortality.

From ten to fifteen, as well as from fifteen to twenty, and in each succeeding decade, the bulk of the mortality occurs in the spring and early summer months. At this period cold is little felt, but it would seem that heat is, either directly or indirectly, for July presents most deaths. The mortality in each of the months, except September, of 1877, is less than usual. October is, as it should be, the month of fewest deaths, and April counts most.

From fifteen to twenty the mortality does not vary much from month to month; the range is only ten. In 1877 there was an observable falling off in the number of deaths in February and October. The first of these months was warmer, drier, with less range of pressure, more northerly and westerly winds, and more fair and clear weather than usual. The leading characteristics of October were a high mean temperature and humidity, with a large rainfall and little east wind.

From twenty to thirty the spring and early summer excess in the death rate is more marked than during the last period. In 1877 there was a reduction in the number of deaths in March, September, October and November—months which were, with other characteristics, warmer than usual. In an able article, entitled "Waves of Heat and Waves of Death," by Dr. B. W. Richardson, published in the *Popular Science Review* in 1865, it is said that "up to the age of thirty years variations of temperature exert no influence on the mortality of the population generally [of England], but after the age of thirty is reached then a fall of temperature which is sufficient to cause an increased number of deaths acts in a given manner—as it may be said, in waves or lines of intensity, according to the years of the people. If we make these lines nine years long we discover that they double in force at each successive point. Thus, if the fall in the temperature be sufficient to increase the mortality at the rate of one person of the age of thirty, the increase will run as follows: One at thirty; two at thirty-nine; four at forty-eight; eight at fifty-seven; sixteen at sixty-six; thirty-two at seventy-five; sixty-four at eighty-four." That the death rate of persons under thirty years of age, and especially in the very young in Philadelphia, is largely influenced by both extremes of temperature, is very clear from what precedes, and the same is true, but less emphatically so, in London, as shown by the laborious analyses of Dr. Mitchell and Mr. Buchan.

From thirty to forty, March, July and December are the months in which the excess in the number of deaths is particularly noticeable. This statement holds good for 1877, except in the case of July—a month in which the deaths were considerably less than usual. The three maxima were observable in the last decade. The variable weather of March, the high heat of July, and the increasing cold of December, are apparent in the death rate among persons from twenty to forty.

From forty to fifty the October rise in the death rate does not increase, but it holds its own until the end of January, when there is a slight abatement, which is replaced by a marked increase in March, toward the end of which a decline begins and continues until the end of June, when the heat is apparent in a slight increase. Except in April and June, in each of the months of 1877 there were fewer deaths than usual.

From fifty to sixty the leading features of the death rate are the same as in the preceding decade. Except in April, October and November, there were fewer deaths than usual at this period in each of the months of 1877.

In persons approaching their threescore and ten years, the growing cold of the winter months makes its mark; and the increase continues until toward the end of April, when a decrease sets in and continues until the heat of July comes, when an increase is observable. A somewhat similar statement applies in 1877, but there were fewer deaths than usual in January and August.

From seventy to eighty there is a marked increase in the death rate from November forward until toward the end of March, when a downward turn begins, and continues until near the end of June, when the heat begins to cause a rise. In 1877 there were fewer deaths than usual in the fall months.

In persons eighty and over the death rate increases gradually from toward the end of October until toward the end of March, when a decrease sets in, which continues until the end of September. In nearly all the months of 1877 the death rate among persons at this period of life was less than usual; in April only was it noticeably more.

Such is a brief synopsis of the leading features of the seasonal mortality at different ages, together with the bearings of particular meteoro-

logical conditions upon it in the city of Philadelphia. From the data given the reader can readily complete for himself any deficiency which he may perceive in the analysis given. All the figures given may be relied upon as correct; they have been prepared with great care, and no little labor has been spent in their preparation.

HYPODERMIC MEDICATION IN CHOLERA MORBUS.

BY JOHN C. PEARSON, M.D.,
Of Ursa, Illinois.

It is often said and written that the result of the treatment of isolated cases is frequently of little or no value in deciding upon the efficiency or non-efficiency of any particular line of therapeutic measures. But, on the contrary, when any plan of medication always, or, at least, very nearly always, is followed by certain definite, favorable and successful effects, we are fully warranted in the conclusion that such effects are the results of the application and use of the plan; that the certain relation of cause and effect is fully established. Most especially may this very justly be claimed when any special plan of treatment has in any special pathological condition been, through long years of trial, uniformly successful.

The writer hereof is led to make these reflections when he takes a long retrospect, of some years, regarding the morbid condition whereto we give the name of cholera morbus, and his treatment of the same.

Some years ago, during that period of a summer when Sirius, the dog star, was in the ascendant, and on one excessively hot afternoon, I was sent for to see a German, and a most esteemed and valued friend, who the messenger said was sick as "de tyful, and he go so dead," imitating, as he imparted this information, the actions of a dying man as near as he could, by closing his eyes, throwing back his head and spreading out his hands with a spasmodic jerk!

Upon my arrival at the house of my patient, and a hasty examination, I would at once, and without the least hesitation, have diagnosed the case one of genuine Asiatic cholera had any cases of that dread disease been prevailing in the neighborhood at the time; for the patient before me had every characteristic symptom of the same to a high degree—at least, such appeared to be the case upon a first and rapid examination; and it was not until I had made a more thorough inspection of the symptoms that I diagnosed that I had an extremely severe case of cholera morbus to combat. He was most severely cramped in the abdomen, legs, arms and feet; vomited, almost incessantly, matter looking like soap suds; had frequent and copious evacuations of rice water appearance from the bowels; hands and arms cold to the elbows, and feet and legs cold to the knees; almost pulseless at the wrist; great drops of cold, clammy sweat stood upon his face, and he was suffering most excruciating agony, as his complaints and outcries, and extreme restlessness and anxious countenance most clearly indicated.

At that time the little hypodermic instrument had not come to be used so much and frequently as it has since the period whereof I write, and I had never used it in cholera morbus, nor had I ever read or heard of it being used in the same; but it occurred to my mind that it *might* give relief; that I would try it; it wouldn't take long to try it, and if it failed, I could resort to other measures. Acting upon this self-made suggestion, I promptly and without delay injected into the subcutaneous tissue of the arm a half grain of morphia sulph. and the fortieth of a grain of sulph. of atropia, and sat down to wait for a few minutes for the result. I had not long to wait, however, for in five minutes' time the cramps, the vomiting, the purging, the jactitation had all begun to lessen, and in twenty minutes more *every one and all of the symptoms had ceased entirely.*

Never before had I been so greatly surprised as I was at the effect I had obtained, and for some time expected a return of the symptoms, having no confidence in the permanency of the good I had accomplished; but there was never a return of any of them, and I absolutely gave my patient no other medicine than that aforementioned, excepting a little for a slight consecutive fever of twenty-four hours' duration.

The results obtained in this case were so very much better than I had dared to hope for, they so quickly followed the administration of the remedy that, for some time subsequently, I was disposed to regard the sudden cessation of all the symptoms as a possible coincidence, but yet felt determined to repeat the treatment, the result of which had so greatly surprised me, the next time a similar case should come under my care. And not many days elapsed before an opportunity was afforded me of further trying the same treatment in a similar and nearly as severe a case. The effects that followed were fully as prompt, decided and lasting; and during the remarkably hot weather of that summer and autumn I had frequent opportunities of further

testing the efficiency of the hypodermic treatment of cholera morbus, and it never disappointed me, though occasionally I would have to repeat the dose before I would obtain entire relief for all of the symptoms. And since that time, ten years ago, I have always similarly treated cholera morbus, and always successfully and permanently so, and generally without the occurrence of consecutive fever.

And for some years past, when I have been summoned to a case of vomiting and purging, I go feeling assured that I will be able to give relief in a short while, with but little trouble and delay, and without bringing into requisition any of the old fashioned and old fogyish therapeutics of past years, such as "broken doses" of calomel, cayenne pepper, rubefacients of turpentine and ammonia, hot bottles, hot bricks, *et id omne genus*, a plan that necessitated twenty-four hours' time, resulted in the patient getting all the skin rubbed off his legs and arms, and sometimes left him with an infernally sore, salivated mouth and swelled tongue, wherewith to curse, in thickened accents, that "d——d doctor" for salivating him so badly!

I have heretofore reported the treatment of one case of cholera morbus, upon the plan herein mentioned, in the REPORTER, but do not recollect of having ever seen any accounts of similar treatment for that disease by other physicians, though I suppose that others may have adopted and practiced it. I have very often pursued the same plan for the relief of long-continued and obstinate vomiting, the result of different causes, and successfully in most of the cases, especially those cases denominated "bilious vomiting."

HOSPITAL REPORTS.

HOSPITAL OF THE COLLEGE OF PHYSICIANS AND SURGEONS, BALTIMORE.

HYSTERIA.

A clinical lecture by A. B. Arnold, M.D., Professor of Clinical Medicine and Diseases of the Nervous System, College of Physicians and Surgeons, Baltimore.

REPORTED BY J. W. PLUMMER-BATES, M.D.

Hysterical Convulsions — Moral Depravity — Self-inflicted Injuries—Vasomotor Disturbances.

This young girl was sent here by a medical friend, from whom the following history was obtained. A few weeks ago she came under his treatment for a sore arm. He found the whole inner side of the left arm covered with an eruption resembling a crop of large-sized pemphigus. Above the bend of the elbow he observed, also, some small, brownish-looking spots, which felt hard to the touch, and proved to be the ends of needles, that were easily extracted. The skin eruption showed little tendency to heal, and as the girl had no means of support she was sent to this hospital. The patient complains of severe pain in the affected arm, which she describes to be of a burning and tingling character. From the shoulder to the tips of the fingers there is almost a complete denudation of the skin. In a few places there still exist some unbroken blebs. The arm is considerably swollen, especially at the elbow joint, which is immovable, and keeps the limb in a state of semi-pronation. During the second night after her admission she was attacked with spasms, but they had already ceased before the house surgeon saw her. On examining the arm, he detected a number of fine punctures on a portion of healthy skin, from which protruded the ends of needles. The girl stoutly protested her innocence when she was accused of having introduced the needles herself. I witnessed one of her convulsive seizures, which was of a decidedly hysterical character. She deliberately threw herself on the bed and began a series of disorderly movements, in which her whole body seemed to be engaged. There was plenty of writhing, twisting and jerking; a hissing noise escaped from between her clenched teeth; the eyes were turned upward, so that only the white could be seen. Occasionally she would scream and stare about, and then point to her epigastrium, which was probably the seat of uneasy sensations. Pressure over the ovarian region did not arrest the paroxysm. The only symptom which remained after the patient had fully recovered was extreme dilatation of both pupils. Very little could be ascertained concerning her family history. She is only eighteen years of age, and has evidently led a wandering and dissolute life. Not the slightest traces of a venereal taint could be discovered on her body. Her menses are regular; all the other functions are normal, and for a person of her position in life she is quite intelligent. She has, however, a downcast look, her movements are sluggish, and her speech has a whining tone.

Hysterical Paraplegia, Hemi-anæsthesia, Analgesia and Trance.

Not long ago a case of hysteria came under my observation which is an instructive example of another and not uncommon form of this malady. The patient is an unmarried woman, about 20 years of age. According to her mother's account, she had given her family much trouble. Among the medley of disorders to which she has been subject I will only mention a few of the more important. For a considerable time she had suffered from neuralgic pains of the back and lower extremities, which suddenly ceased on the occurrence of paraplegia and frequent retention of urine, that confined her to bed for many months. At present no motor paralysis exists, but there is hemi-anæsthesia of the whole of the right side of the body, analgesia of the face of the same side, and dorsal aspect of both extremities. For instance, when a needle is deeply thrust into the skin, or when the flame of a candle is held near the part, she evinces no

signs of pain. She also cannot distinguish thermal differences; cold and warm substances placed on the affected side only produce the sensation of faint tactile impressions. Sometimes she is overcome by a deep sleep, which alternates with a condition resembling trance. After coming out of this somnolent state she is restless, peevish and morose, moans, and behaves like a crabbed child that cannot be pacified, and finally she insists on being taken to her mother, for whose fondling and caresses she seems to crave.

Hysterical Asthma—Convulsive Attacks and Delirium.

You will probably recollect that at a former clinic I introduced a boy 15 years of age, who suffered from repeated attacks of asthma, which differed from the ordinary spasmodic type, and could not be traced to any recognizable disease of the thoracic organs. The only other symptoms which accompanied the extreme oppression of breathing, and disappeared with it, were a tumultuous action of the heart, and a severe pain over the cardiac region. The boy had been afflicted with these seizures for the last two years, and during that time the real nature of his disease could not be satisfactorily determined. Since then another group of very significant symptoms developed, that greatly helped to clear up the diagnosis. The labored respiration, the pain and violent action of the heart still open the scene, but these symptoms are now quickly replaced by a semi-unconscious condition and nonrhythmical convulsive movements. At intervals he is delirious, yells and calls for help, then suddenly his face lights up in smiles, he rises from his bed, nods his head, gesticulates with his fingers, and as a finale bursts into a fit of sobbing. It is noteworthy that the repetitions of these hysterical attacks exhibit a uniformity in the order and character of the symptoms. The mother of the boy thinks that his ailment was caused by one of his companions who had played some trick upon him.

However well marked these cases of hysteria really are, yet it cannot be said that they are typical examples of this disease; for hysteria is protean in its manifestations, and strange enough, its apparently unessential symptoms are the most significant. And, indeed, how is it possible to give a true clinical picture of a malady that simulates nearly every known disturbance of the nervous system; affecting sometimes the intelligence, though more frequently the emotions and the will; inducing derangement of common and special sensation, and of the motor functions, and thus presents disorders variously combined and manifold in their character. It is also a peculiarity of hysteria that some of its symptoms may be merely of an isolated or localized description, such as sudden blindness, asthma, vomiting, etc., or counterfeit disease of the spine or of the joints. In view of the remarkable variability and complexity of the hysterical symptoms, as well as their frequently sudden appearance and evanescent character, it is not surprising that no distinctive lesion of this disease has as yet been discovered. The old notion that hysteria, as its name indicates, always depends upon some uterine derangement, and is therefore limited to the female sex, is now generally abandoned. By nearly common consent this disease is provisionally classed among the neuroses, with which it has many points of agreement—chief among them being a peculiar susceptibility of certain portions of the nervous system to functional derangement, or, speaking more specifically, there probably exists a morbid excitability of the cerebro-spinal axis which readily disposes to reflex action from slight irritation. Of course, suppositious reasoning of this sort goes but a little way to indicate the pathology of neurotic affections; hence, for the want of a more substantial explanation, we must be content to retain the misnomer, hysteria, as merely denoting a tolerably well defined disease, based upon clinical observations.

The diagnosis of hysteria would be an easy task were it not for the frequent occurrence of isolated symptoms of this disorder unattended by others that usually serve as a clew. This is well illustrated by the cases I have brought before you.

Let us compare their symptomatology, and inquire on what grounds the diagnosis of hysteria is founded in each of them, although their morbid phenomena do not seem to have much in common. Bearing in mind the mental peculiarities, the impulsive proclivities and incalculable conduct of the hysterical, the repeated wounding of the arm in the case of the girl would be quite in keeping with these morbid characteristics, and if any doubt remained of the correctness of this inference it would at once be removed after having witnessed the significant convulsive attacks. The tendency to malingering, of which the hysterical are accused, receives its true interpretation when considered in connection with other signs of the malady. It is not so much the concrete example as the evidence it affords of a deterioration or perverseness of the volitional energy, which is of importance. From the same source originates, also, that moral obliquity observed as an occasional phase of hysteria, which may consign the victims to the disreputable and even dangerous classes of society. There is no trenching upon the province of the moralist when the clinician acknowledges an intimate relation between the hysterical diathesis and unhappy propensities. Many an incorrigible female who is unfortunately under the sway of the hysterical element, may be for a length of time a puzzle as well as a source of mortification to her family and friends, until the enlightened physician recognizes the true state of the case.

Applying these considerations to the unraveling of the psychical condition of our patient, it becomes less difficult to account for the reprehensible conduct and the practices of dissimulation and imposture of one of her age and sex. Eminent authors, among whom Griesinger and Maudsley may be mentioned, consider hysteria a form of insanity. That hysteria may develop into insanity there cannot be a doubt; but the medical profession does not recognize this affection as a mental disease when short of unmistakable evidences of unsoundness of mind. The cutaneous eruption of the arm, and the swelling

and stiffness of the elbow joint, must be considered as incidental occurrences resulting from the needle punctures that wounded the so-called trophic nerves, or at least occasioned vaso-motor disturbances.

Since the publication of Weir Mitchell's admirable work on "Injuries of Nerves," we have become acquainted with skin affections and changes in other tissues that are produced by the wounding of superficial nerves. No one who is at all familiar with the physiognomy of an ordinary hysterical fit would hesitate to declare the convulsive seizures of the girl to be of that description. There are points of resemblance between the hysterical and the epileptic convulsion, but hysteria always impresses its own stamp upon symptoms that betray their true character. The hysterical paroxysm is often the culminating effect of a provocation; the convulsions present only a quasi appearance of tonic or clonic contractions, and seem to be not completely beyond the control of the will; consciousness is not entirely in abeyance; nor does the hysterical fit, with the exception of those rare instances of hystero-epilepsy, present that horrible and repulsive sight which is so characteristic of the epileptic seizure. Certain minor differences deserve also to be mentioned. The epileptic cry occurs only at the onset of the attack; the hysterical screaming often continues throughout the whole paroxysm. Biting of the tongue is unusual in hysteria The epileptic comes rapidly out of his convulsive condition, and may then either fall into a heavy sleep or be speedily restored. Hysterical convulsions, as a rule, last much longer and frequently terminate after a fit of laughter or sobbing.

The second case presents the comparatively rarer symptoms of hysteria, such as motor and sensory disturbances, and trance. Their hysterical nature is principally revealed by the clinical history of the case. It is an important hint to diagnosis when paralysis occurs in a nervous female after some mental shock, or when it is preceded or accompanied by other well known hysterical symptoms. The obstinacy of these nervous affections is sometimes very great, which seems to be quite at variance with the supposition that no palpable lesion exists, but the latter is supported by the curious phenomenon that hysterical patients who were bed-ridden for a great length of time, with paralysis, have recovered the use of their limbs instantaneously, under the influence of a mental or rather a moral impression.

No little embarrassment was felt, in the case of the young lad, to interpret correctly the respiratory and cardiac symptoms that preceded the development of the more recognizable features of hysteria; and among the latter the apparently trivial event of sobbing, which seemed to relieve and quiet the nervous commotion, served as a valuable guide to diagnosis.

There is certainly some risk in allowing a too great latitude to the term hysteria, and it is especially important to remember that not only are the earliest stages of organic affections of the nervous system frequently masked by symptoms of an obscure character that may easily be mistaken for hysteria, but even the slow development of chronic diseases in females, such as phthisis pulmonalis and cancer of internal organs, may lead to a similar diagnostic blunder.

A carelessness in the use of the words "hysterical" and "nervous" generally prevails. When we speak of a nervous temperament we mean an exaggerated excitability of the nervous system which is still within the limits of health; but when, in addition to this certain well understood phenomena of a neuropathic character are apt to be developed we recognize the hysterical disposition. This distinction, however, cannot always be carried out, and practically it is of little importance.

In regard to the treatment, I share the opinion of those who look upon the hysterical as actual sufferers. From my personal experience I have nothing to add to the well intentioned suggestions and other edifying reading you will find in the books concerning the educational and disciplinary management of children who show a hereditary tendency or predisposition to hysteria. The "moral therapeutics" of established hysteria, I am inclined to believe, consists of that subtile influence exerted by a certain address or aptitude on the part of the physician, which secures the confidence of his patient. This is probably the reason why some practitioners are particularly popular with the hysterical. It is hardly necessary to allude to the importance of paying attention to the functional derangements of the female generative organs in cases of hysteria. In a great number of cases no such derangements exist, and according to my experience, the instances in which the skill of the gynecologist was alone sufficient to cure form the exception. Many hysterical persons require a general tonic treatment, which suggests the use of iron, strychnia, phosphorus, cod-liver oil, etc. Whether these remedies, however judiciously selected, exercise any direct beneficial influence on hysteria proper, is another question; for a considerable number of nervous and hysterical people present the appearance of perfect health. Unaided nature comes promptly to the rescue of the hysterical convulsion, and the only service which the hastily summoned physician can render to the patient is to ward off mischief and to discourage the officious meddling of spectators. Among the latter I include the popular practice of forcibly closing the mouth of the patient and throwing buckets of cold water over the body. Electricity has recently been employed with success in aphonia and other forms of local hysterical paralysis. The bromides are now extensively used in hysterical spasms, and always deserve a fair trial. Of late I have given preference to the bromide of zinc, beginning with gr. $1\frac{1}{2}$ twice daily, and gradually increasing to grs. 4. It must be administered in pillular form. The electric brush is especially valuable in anæsthesia. In praise of the traditional anti-hysterical remedies, this much can be said, that it is far preferable to prescribe assafœtida or valerian than to expose hysterical females to the dangerous fascination of alcoholic stimulants, which, undeniably, produce a calming effect on the many disagreeable sensations from which these patients constantly suffer. For a similar reason it is advisable to use narcotics

sparingly, though they are sometimes indispensable. Every one has some favorite combination from this class of drugs, which the hysterical patient is recommended to keep on hand for emergencies. The following I have found to answer the purpose very well:—

℞. Ext. valerian, fl., ℥j
Ext. sumbul, fl., ℥ss
Tinct. castorei, ℥vj
Spt. ether. chloric,
Syr. aurant. cort., āā ℥iij. M.
Sig.—One teaspoonful, frequently repeated.

Treatment of Cholera Infantum.

On this subject Dr. G. A. Moses observes, in the St. Louis *Courier of Medicine*—

Without combating at present the contrary recommendations, suffice it to say that the plan of Dr. Dewees, described in his admirable treatise on Diseases of Children, has proved more satisfactory to me than any other. That is, at the outset, small doses of calomel, one-tenth to one-fourth of a grain every hour until the character of the evacuations is improved. In addition to this, when the stomach is very irritable, a mixture containing a small quantity of calcined magnesia in cinnamon water, or a weak, very cold solution of bicarbonate of soda, taken every fifteen minutes, will frequently answer an excellent purpose. No food should be permitted, not even the breast, until the choleriform symptoms shall have been much diminished. Cold egg water, made by breaking the white of a fresh egg into a glass of water and tossing this from glass to glass until thoroughly mixed, made very cold with ice, may be administered in teaspoonful doses at short intervals. This will allay thirst, and not irritate. Food is of no service, but of harm, as digestion is impossible.

When the mucous infiltration shall have subsided, as will be evinced by diminished frequency of discharges and the appearance of the yellowish-colored succus entericus, the calomel may be given at greater intervals, and a simple astringent mixture, such as the mistura creta, with or without a very small quantity of opium, may be administered; but both for the purpose of relieving pain, securing sleep, and allaying nervous irritability, I prefer the bromides or chloral.

Treatment of Nocturnal Seminal Emissions.

In an article in the *American Practitioner*, Dr. F. J. Bumstead gives the following directions—

In all cases of frequent nocturnal emissions the genital organs should be examined, and whether phimosis exists or not, if the prepuce be long and redundant, circumcision is to be recommended. A very marked varicocele may also render surgical interference desirable.

The hygienic rules to be given to the patient are very simple. It is better that the most substantial meal in the twenty-four hours should be taken at noon; the supper should be light, and food and drink be entirely avoided in the evening; the bed-chamber should be well ventilated, a hair mattress preferred to a feather bed, and much covering avoided. The patient should sleep upon his side, and not upon the back; a small pillow placed between the knees, so as to separate the thighs and prevent the scrotal organs from becoming heated, is sometimes desirable; and the patient should rise as soon as he wakes, emissions occurring most frequently during the semi-consciousness of the early morning nap.

Tobacco in every form should be prohibited, since it not only increases the general irritability of the nervous system, but appears to have a direct influence in diminishing the tone of the genital organs, and thus favoring seminal emissions.

Above all, as already stated, the mind of the patient should be distracted from his complaint by constant occupation, and his general health be promoted by a plain but nourishing diet, and by daily outdoor exercise, not carried to fatigue, since it is found by experience that when the strength is exhausted an emission is more likely to occur.

Many of these patients also have constipated bowels, and means should be taken to secure a daily stool.

As a rule, no other measures than the above are required. It is to be understood, however, that any weakness and irritability of the nervous system may require the administration of tonics, a change of climate, etc. For this purpose I have found the two following prescriptions of good service:—

			Grams.	
℞.	Ferri et quiniæ citrat.,	℥iij	12.	
	Strychniæ sulph.,	gr.j	.06	
	Acidi phosphoric. dilut.,	℥ss	15.	
	Syrup. aurantii,	℥ij	75.	
	Aquam ad.,	℥iv	145.	M.

Sig.—A teaspoonful (5.00) in water, after each meal.

			Grams.	
℞.	Strychniæ sulph.,	gr.j	.06	
	Acidi phosph. dilut.,	℥iij	90.	M.

Sig.—A teaspoonful (5.00) three times a day, after eating.

The tincture of the chloride of iron, and also ergot, have been supposed, and I think justly so, to have a special tonic effect upon the genital organs; but they must be given in large doses, as, for instance, from half a drachm to a drachm (2.00–4.00) of either the tincture of iron or the

fluid extract of ergot (Squibb's), in water, after each meal. They may be combined, as in the following prescription:—

			Grams.	
℞.	Tr. ferri chloridi,	℥ iij	90.	
	Ext. ergotæ fl. (Squibb's)	℥ iij	90.	M.

Sig.—A teaspoonful (5.00) in water, after each meal.

As a direct means of diminishing the frequency of the emissions, however, the following is often found to be most efficacious:—

			Grams.	
℞.	Potassii bromidi,	℥ j	30.	
	Tr. ferri chloridi,	℥ j	30.	
	Aquæ,	℥ iij	90.	M.

Sig.—From one to two teaspoonfuls (5.00–10,00), in water, after each meal, and at bedtime.

Mention has already been made of the advisableness of circumcision when the prepuce is long. It may also be found, upon the introduction of a sound, that the urethra is over sensitive, especially in the prostatic region. In such cases the introduction of a cold sound of full size, at first every third or fourth day, and afterward with greater frequency, will generally afford relief to the hyperæsthesia. I sometimes inject into the prostatic urethra about ten drops of a solution of nitrate of silver of the strength of twenty grains (1.30) to the ounce (30.00) of water, by means of a deep urethral syringe, or Guyon's flexible catheter and syringe. The severe cauterization with the *porte-caustique* of Lallemand should by all means be avoided.

The Advantages of Alcoholic Surgical Dressings.

In the *Western Lancet*, July, Dr. A. E. Regensburger brings forward some evidence to show that alcoholic dressings are a prophylactic against erysipelas. He adds:—

Alcohol possesses three advantages over many other dressings, which may be briefly formulated. 1st, simplicity; 2d, cleanliness; 3d, absence of all odor. Unquestionably, something that cannot be said of many of the complicated dressings in use at the present day. To convince one's self of the correctness of the above assertion, having used or having seen it properly employed for a short space of time, is all that is requisite. In applying this dressing all that is necessary is some alcohol and some charpie—no spray producers or other elaborate or costly paraphernalia. The piece of charpie is moistened with alcohol, and the wound, after being otherwise properly arranged on general surgical principles, is covered with it. The dressing is changed two or three times in twenty-four hours, care being taken to keep the charpie continually saturated with alcohol. In France a great many use *eau de vie camphrée* instead of alcohol alone. Whether the camphor adds anything to the efficacy of the alcohol I am not prepared to say; but I am rather inclined to think that it does not. Contrary to what one might suppose, the pain occasioned by the application of alcohol to a wound is not severe. The first two or three applications cause a slight smarting sensation, after which it is *nil*. Possessing all these advantages, and very few drawbacks, we trust that this method may receive a trial by the profession on this coast, and if it responds to the hopes entertained of it, that it may be used universally.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——The Atlas of Histology, by Dr. E. Klein and Mr. E. Noble Smith, part v., embraces striped and unstriped muscular fibre and medullated nerve fibre. The illustrations are exquisite, as usual, the text brief and clear. Philadelphia, J. B. Lippincott & Co.

——The President's address before the American Medical Association, at Atlanta, was by Dr. Parvin, and his topic was "Philosophical Problems in Medicine." It is now out in pamphlet form. That it is learned, nobly inspired and gracefully written, all will find who read it; that it solves any of the problems it touches, nay, that it even states the more important of them fairly and in the true spirit of science, we are forced to deny. For instance, the logical necessity of assuming intelligent design in order to explain the adaptations of nature is wholly rejected now, even by many theologians.

——Dr. John Van Bibber, of Baltimore, read a paper last April, before the Medical and Chirurgical Faculty of Maryland, which that body refused to publish, so the author now issues it himself. Its title is "The Future Influence of the John Hopkins Hospital on the Medical Profession of Baltimore." Why the Faculty wouldn't publish, may be judged from the following extracts: "If we regard the present state of the medical profession in this city, we see it in almost the same condition as we might expect to find the profession of a much more obscure and less populous community. * * * Having no centre of observation and research, the literary efforts of medical men here have been meagre, scanty and unimportant. Though some few have attained eminence, it has been, with one exception, merely local, and the efforts of these students have been lost in the routine of exacting and laborious duties. During the last fifteen years the standard of medicine here has even descended lower."

The Faculty should have remembered that if these statements are without foundation they will be without effect; and if true, they deserve publicity. In either case their timidity about meeting the issue is not in their favor.

BOOK NOTICES.

Lessons in Gynecology. By William Goodell, A.M., M.D., Physician of Preston Retreat, Professor of Clinical Gynecology in the University of Pennsylvania, etc. Philadelphia, Pa., D. G. Brinton, 115 South Seventh street, 1879. pp. 380. Illustrated. Price, cloth, $3.00; leather, $3.50.

Philadelphia, the oldest seat of medical instruction in the United States, has given the profession, during the present century, but three works on diseases of women, the authors of these works being Dewees, Meigs and Hodge. Nearly a score of years has passed since the first edition of Dr. Hodge's treatise was issued, and the silence of Philadelphia teachers, that had become painful, if not punishable, is now broken. And he who breaks this long silence is also a teacher in the honored University in which Dewees and Hodge were themselves instructors, but teaching diseases of women very differently, indeed, from the way in which they were taught by his illustrious predecessors. It is well that some men who hold prominent positions are sensible of the truth that they are debtors to the profession, and that censure, both public and private, is sure to come upon them if they take, through a long series of years, the honor and the rewards of those positions, and keep their treasures of knowledge and experience merely for their classes and their private gain.

Dr. Goodell's handsomely printed, neatly bound volume (of nearly four hundred pages), is dedicated to S. Weir Mitchell, M.D., and is entitled *Lessons*. Is the title wisely chosen? A few years ago a translation was made of the *Leçons* of Velpeau, and published under the name of *Lessons*. A New York reviewer, who did not thereby end his life, criticized very severely the term—a reviewer sometimes is thought nothing unless critical—condemning it, however, chiefly, our memory not being in fault, as a mis-translation of *Leçons*, though really the error is more apparent than real, for probably our word lesson is simply that Anglicized. As several of the papers composing the volume were occasional contributions to medical journals, the term clinical lectures, which would be appropriate to most, would not include these. So let Lessons remain, for we believe the word has been wisely chosen. It is one of the author's rare gifts, acquisitions we had better say, to be able to use the right word; a homely word it often is; again, a word so little in use as to be almost if not quite obsolete, but still generally the right word; a word carrying a light so clear that the thought is made plain. He calls a spade a spade; yes, and for this matter too, he calls a *spayed* a *spayed*, unless Albert H. Smith's criticism at the last meeting of the Pennsylvania State Medical Society shall induce him to renounce such great plainness of speech!

The first of the twenty-nine lessons constituting the book is devoted to *Gynecological Instruments*. We make no remarks upon the collection of instruments advised by Dr. Goodell, save that we would include Emmet's curette forceps and Neugebauer's speculum in the list, and exclude Eliot's repositor, which we believe is a good instrument to avoid using. We must confess too, to a moment's doubt of the author's rhetorical infallibility, when we come to the word "applicating," on page 22; a word made for the occasion from the obsolete verb applicate; applicating is, however, no more objectionable than eventuate, which has found a permanent place in American English.

The second lesson is upon *Caruncle and other Affections of the Female Urethra*. The chapter is excellent throughout; excellent in language, clear and valuable in instruction. One must be struck with the apparent contradiction between the statement here made by Dr. Goodell, as to prolapse of the mucous membrane of the urethra, occurring most frequently in children, and that of Dr. Skene, *Diseases of the Bladder and Urethra*, that the few cases of the accident he has seen were in women over fifty years of age. Doubtless Dr. Goodell's statement is correct, and a conclusion drawn from Dr. Skene's experience would be erroneous. For our own part, we have never seen such prolapse, except in children. We do not quite coincide with Dr. Goodell in the treatment of the affection—"snipping off a strip of the prolapsed mucous membrane, or one or two applications of nitric acid in a narrow streak around its whole circumference."* That may do in the slightest cases of the displacement, but when you have a tumor the bigness of the end of the thumb, and tormenting vesical distress, with partial retention of urine, *tempus non eget acido nitrico vel strip-o*, speaking after the manner of the Roman poet. Then a catheter must be introduced to relieve the bladder, and retaining the instrument, ligate as proposed by Seguin, the mass around it, a mass already possibly threatening to slough.

* And yet we are inclined to put an interrogation point on p. 28, after "visually inspect."

The third lesson, *Vesical Diseases of Women*, contains in eight or nine pages a wonderful amount of plain, practical, invaluable instruction.

Fistulæ of the Female Genital Organs are considered in the fourth lesson. We venture the assertion that no matter how much one may have studied the abundant literature of these fistulæ, nor how great his practical experience in their treatment, he cannot read this chapter without acquiring some new knowledge; while to the student entering upon the subject for the first, there is given as good a presentation of it as can be found anywhere, one that will readily and indelibly fix itself in his mind.

The fifth lesson includes *Closure of the Vulva for Incurable Vesico-vaginal Fistulæ; Tumors of the Vulva.* In introducing the history of a case of incurable vesico-vaginal fistula, in which he proposed (and subsequently executed), closure of the vulva, and perforation of the recto-vaginal wall, so that the urine should be discharged into the rectum, and thence evacuated, Dr. Goodell remarks, "I am emboldened to recommend this step, because a very analogous operation had succeeded in the hands of my friend, Dr. W. W. Keen. His patient had an incurable vesico-vaginal and recto-vaginal fistula. * * * I aided him in closing up the vulva, and he has since told me that she is now able to hold her urine in the rectum for hours before voiding it." But it ought to be remembered that Da Costa Dwarte, *Des Fistules Génito-urinaries chez la Femme*, in 1865, proposed the very operation executed by Dr. Goodell, and that Baker Brown had demonstrated in 1860, in the London *Lancet*, April 19th, 1862, page 402–3, the same fact which Dr. Keen subsequently did.

The sixth and seventh lessons are upon *Lacerations of the Female Perineum.* We miss any notice, in the description of the secondary operation, of the admirable method of Dr. E. W. Jenks, late of Detroit, now of Chicago, for denuding the surfaces to be brought in union. We find, too, that Dr. Goodell is an advocate for keeping the bowels confined after perineoplasty, an old and general practice which, however, some excellent authorities, Lawson Tait, for example, are discarding.

Chronic Metritis and Endometritis are discussed in the eighth lesson. The chapter is practical, contains many useful formulæ, and amply repays, not only careful perusal, but study.

Versions and Flexions of the Womb, Dilatation of the Cervical Canal, Pessaries and Abdominal Supporters bring us to the fourteenth lesson, which is upon *Prolapse of the Womb.* When we read, in reference to supporters, this able University teacher's words, "Within a few years I have become convinced that much advantage can be gained from a judicious use of braces as adjuvants to the treatment of uterine disorders," we could not help thinking that if ever the graves of the dead could be disturbed by the utterances of the living, these words would surely disturb the rest of that venerated teacher, Dr. Hugh L. Hodge. How often, how earnestly he declared to his classes that the cavity of the abdomen was a *plenum*, and any pressure upon the abdominal walls from braces, bandages and supporters, so far from remedying, would surely aggravate uterine displacement!

Prolapse of the Womb, considered not only in the fourteenth, but also in the fifteenth lesson, presents some controverted points, especially since the utterance of Dr. Emmet in his recent work, to the effect that amputation of the cervix, except in cases of malignant disease, is malpractice, a declaration that the profession will be very slow to accept. This and other matters of dispute would require more space and time for proper consideration than we have at our command.

Laceration of the Cervix Uteri is the subject of the sixteenth lesson. The profession is debtor to Dr. Goodell for the remarkably clear exposition of this important and not uncommon lesion and its treatment.

The seventeenth lesson has for its subject *Cancer of the Womb.* Lord Bacon urged that physicians should study methods of curing diseases regarded as incurable. Cancer presents a most important field in which to exercise the great philosopher's injunction. Dr. Goodell presents some most interesting cases in which local treatment materially retarded the disease, and others in which it was apparently permanently cured. Certainly this darkest chapter of uterine pathology becomes less dark by the light of his experience.

One of the most valuable of the *Lessons* is the eighteenth, *Vegetations of the Endometrium.* The non-malignant form of these vegetations, *endometritis hyperplastica*, generally readily yields to the curette and swabbing the surface with a strong tincture of iodine. Dr. G. states that the dull wire curette of Thomas sometimes fails, and then he uses Sim's sharp curette. We confess that we prefer Récamier's instrument to either.

He states, "whenever the redundant mucous membrane hangs down in spongy folds, I have

found nothing to remove it so well as a small pair of fenestrated polypus forceps." We were in the habit of using such forceps for this purpose until two or three years ago we got a pair of Emmet's curette forceps, and since using this instrument find it unnecessary, in many cases, to resort to the curette itself.

Uterine Polypus and *Fibroids* are the subjects of the nineteenth and twentieth lessons, while the treatment of the latter is considered in the twenty-first lesson.

The twenty-second lesson is upon *Spaying for Fibroid Tumors of the Womb, and for Other Disorders of Menstrual Life.* This important subject is discussed ably and impartially; valuable tables of the operations, and of the effect of double ovariotomy upon menstruation, are given, and every help now possible given for reaching a just conclusion. While not yet prepared to give our adhesion to the operation, the investigations of Dr. Goodell certainly present it in a more favorable light. In the Edinburgh *Medical Journal*, June 1879, Prof. Simpson narrates a successful case operated upon June 1878. On the other hand, is it not probable there have been unsuccessful cases that have not been reported, or that the percentage of recoveries, of cures partial or complete, and of deaths, is still unsettled?

Ovarian Cystic Disease and its Treatment are faithfully presented in the twenty-fourth lesson, while *Vaginal Ovariotomy* is the subject of the twenty-fifth.

The next lesson is entitled *Nerve Tire and Womb Ills;* or the *Relation of Neurasthenia to Diseases of the Womb.* To our notion the *alias* is the better title, and under it the paper appears in the third volume of the Transactions of the American Gynecological Society.* The profession is already quite familiar with this admirable contribution. He who puts in practice the instruction here given will rescue many a poor sufferer from chronic invalidism, promote her happiness, prolong her life.

The twenty-seventh lesson gives us *Practical Hints for the Prevention of Uterine Disorders;* hints that are, indeed, of the utmost importance. Then we have in the twenty-eighth a discussion of the *Relation which Faulty Closet Accommodations bear to the Diseases of Women*—not "a dainty dish to set before" any one, it might be imagined, but yet delicately, plainly, usefully presented.

The final lesson is entitled, *The Sexual Relations as Causes of Uterine Disorders.* These are referred to as *Conjugal Onanism, and Kindred Diseases.* But is it a proper use of language to indicate that onanism, conjugal or not, is a disease, as is implied in the addition of "and kindred diseases?" The onanism may, and does generally, induce disease, but it is a voluntary act, and therefore can hardly be classed as itself a disease. However, let this pass. The lesson is an exceedingly valuable one, dealing with most delicate topics, topics having most fundamental relations, not only to good health but to good morals, and yet considering them with plain speech and wise counsels. Sexual excess, the fountain of countless miseries and immoralities, has no more fruitful source than in the unenlightened imagination, the unchecked and impure fancies of youth. The growing boy frequently passes into his physical manhood ignorant of the womanly nature save as he learns it from obscene books or obscene companions. By and by he enters married life, possibly continent to that time, and then gives loose rein to the imperious passion that has grown with his years and strengthened with licentious imagination and lascivious dreams, so often believing that woman is altogether such an one as himself. Most heartily do we wish a truer knowledge of the womanly nature and the womanly character could be imparted to young men! Such a work as *Acton on the Reproductive Organs*, if not put in Sunday-school libraries, ought to be faithfully read by every youth entering manhood. Knowledge then and thus given would do a vast deal toward repressing licentiousness in its germs, whether that licentiousness be in the home or in the house of prostitution.

But we must bring our notice to a close. Dr. Goodell's book is one of the most valuable ever given the profession. It is a book that a doctor cannot help reading; and reading cannot help understanding; and understanding cannot help obtaining much knowledge of constant utility in his professional duties.

Such clear, vigorous English as Dr. Goodell uses is not found in all the works of medical libraries. We do not know his superior as a writer. Coleridge, we believe, remarked of Luther that his words were half battles. Dr. Goodell's words are whole torches, making always and everywhere his thoughts luminous.

We have but one regret to express as to the book, and this regret is that there is not more of it.

——Dr. J. Marion Sims' article on "Epithelioma of the Cervix Uteri," has been reprinted in pamphlet form. (Wm. Wood & Co.)

* Annual Address by the President.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Half-Yearly Compendium of Med. Science,	**2.50**
Reporter and Compendium, - - -	**7.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**8.25**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

PHILADELPHIA, PA.

VETERINARY MEDICINE AS A CAREER FOR YOUNG MEN.

We have before us a pamphlet, entitled "An Appeal to the Citizens of Pennsylvania for the Foundation of a Veterinary Department in the University of Pennsylvania."

This Appeal is timely, able, and ought to be promptly successful. It sets forth in strong, almost startling, language the necessity for an improved condition of veterinary science in the United States, on grounds at once humanitarian and economical; and also the advantage to the young men of this country in thus opening to them a career new, beneficent and profitable. Let us briefly review these arguments.

In 1870 the money value of the live stock of the United States was appraised at a little less than $2,000,000,000—two thousand millions of dollars. The most experienced stock owners estimate the loss annually from preventable and curable diseases at from 2 to 7 per cent.; in other words, at from forty million to two hundred and forty million dollars every year! Hog cholera alone, a distinctly preventable disease, taxes the Mississippi Valley at from $20,000,000 to $40,000,000 almost every year. The loss in the single State of New York from epidemic abortion in cows has reached as high as $10,000,000 in a single year. The epizooty in horses, in each of its several visits to the United States, has been estimated to have reduced the national wealth over $50,000,000. The immense interests involved in our shipments of live horses, cattle and sheep to Europe stand in hourly peril of destruction, from the dread of European powers at having epidemic diseases introduced there. These are but a small part of the facts and figures which the "Appeal" before us marshals to prove the urgent call for immediate and thorough instruction in veterinary science in this country.

Secondly, we may refer to its humanitarian aspect. The prevention of suffering in the lower animals as a principle of morals is a glorious development of modern civilization; it broadens sympathy to all that can feel; it extends charity to the alleviation of every form of suffering; and it does so, not out of superstition, but from a growth of purely ethical considerations. Hence it is that the Societies for the Prevention of Cruelty to Animals have taken an active participation in the furtherance of the study of veterinary medicine. The "Appeal" is largely made up by an address by the President of that Society in this city, and it is published under the auspices of the Society. Every one who has traveled much has witnessed the needless brutality to sick animals which prevails on cars, in public stables and on the road; and worse yet is the ignorant cruelty, the mediæval barbarity, which the cow leeches and horse doctors of this country inflict on their four-footed patients, under the pretence of treating them for disease. The gross neglect of every kindly consideration for their stock in the swill-milk stables of New York and the hog pens of the western distilleries have been matter of general newspaper comment. All this could be amended by a proper veterinary education of the profession and the masses.

The "Appeal" most justly stigmatizes the sort of contempt with which the profession of

veterinary science is regarded in the United States. It reminds the reader that in Europe the educated veterinarian is respected and recognized as a man of science; that men of position and liberal culture, graduates of the most famous universities, have taken it up as their life work, and have shown it to be as dignified, useful and noble as any profession whatsoever, as any department of business.

Hence it is that the appeal is made to young men of good preliminary education and prospects to qualify themselves in veterinary medicine, rather than to enter into the over crowded, underpaid, uncertain business of the ordinary M.D. More certain pecuniary returns await them, and a greater probability of fame and fortune. Just now this advice is golden. It requires no prophet to predict that in another score of years thousands will be turning their attention to veterinary studies, while now the field is wide and the laborers few; competition is almost unknown, and all the honors are open for the earliest aspirants. Congressional and legislative bodies are beginning to appropriate money by the tens of thousands of dollars every year to investigate and prevent epidemics among stock, driven thereto by the clamors of farmers and stock shippers. It will not be long before the American public awakes to the need of veterinarians of the very highest education. Who will be the first to secure the honors and emoluments of this new opening for young men?

With this general improvement in the education of veterinarians in this country must go, *pari passu*, the instruction of the mass of farmers and stock owners in the sanitation and domestic treatment of animals. And it is certainly a subject of congratulation that the very best book on this subject—acknowledged to be so by the leading English and American authorities—is that by an American physician, Dr. L. V. Tellor. Of this, the leading English authority, the *Live Stock Journal* of London, says that after careful examination it can say of it that "it is the best book of the kind we have yet seen."

THE NEED OF MORE BACKBONE ON THE PROSTITUTION QUESTION.

An instance of the feeble and timid style in which medical writers of this country speak of the legal control of prostitution, is exhibited in the Detroit *Lancet* of recent date. In a three-column editorial the subject is handled with gloves of double thickness and extra lined. The editor deprecates strong speaking on the subject. He can "scarcely accept the clamor of either side as the indication of any proper course of action;" and he makes the sage and profound observation, "If only we could engage all the children of the land in honest, worthy pursuits, we would be certain that there would be little demand for prostitutes by the next generation." Very true, most sapient moralist! And so also there would be little demand for prisons or workhouses, for preachers or for doctors. No doubt, if we could introduce the millenium at once, we should be quite virtuous.

But in his own suggestion for the doing away with prostitution the learned editor transcends himself. It is so striking, that we quote it in his own words:—

> There is one law that would be efficient, viz., one that would place adultery on the same ground as murder, or even stealing. To punish all adulterers by imprisonment and hard labor would wonderfully purify society. The enactment and enforcement of any such law is, of course, in the present state of morals, simply chimerical. Nevertheless, we think that the advocates of law would do well to work toward the above end. The attainment of such an end means a far higher respect for *humanity* and human rights than has ever held sway upon the earth.

This is a fair indication of the amount of knowledge with which most writers approach this subject. We have not at hand the statutes of Michigan; but if there is not among them one which makes adultery a felony, punishable with imprisonment, and a more serious crime in the eye of the law than many cases of stealing, then we will give odds that Michigan is the only one among Christian commonwealths that is without it. We will say, for the information of that writer, that Pennsylvania has such a law, and that it is enforced, and that many a man is now in durance vile in this State for breaking it;

but for all that, and in spite of this "chimerical" morality we enjoy, the professional prostitutes in Philadelphia are counted by the thousand, and any night he chooses he can pick them up by the dozen on our most prominent streets.

The editor of the Detroit *Lancet* knows perfectly well that there is not a regular medical journal in England, or on the Continent of Europe, that opposes the laws for the regulation and sanitary supervision of prostitution; he knows that he cannot name six physicians in Europe, of the least prominence, who have ranked themselves against those laws. He knows, too, that the medical profession has the best chance to judge of the effects of those laws, and he cannot deny that its expression is that of pure, unprejudiced, philanthropic men. Yet in all this he sees no "indication of any proper course of action!" If this is not cant or cowardice, what is it?

Notes and Comments.

Therapeutical Notes.

SULPHUR IN ACNE PUNCTATA.

The acne which occurs on the face of young persons is often very distressing to them. Dr. J. G. Parsons tells, in the *British Medical Journal*, a simple and efficient remedy. It is to dust the face with pure precipitated sulphur every night, with an ordinary toilet puff. This will usually effect a cure in about a week.

CERIUM OXALATE IN PERTUSSIS.

The latest specific in whooping cough is the oxalate of cerium. It is given in doses of gr. ½–2, before breakfast, once daily. Dr. T. Clark has recommended it in the *Practitioner*, and a New York physician, Dr. Morje, has reported favorably from its use.

QUININE IN GOUT.

From his experience in a half a dozen cases, Dr. C. W. Schœneman (*Pacific Medical Journal*) believes that quinine will cut short an attack of gout. He gives:—

℞.	Quiniæ sulphatis,	gr.iij	
	Sodii bicarb.,	gr.xij.	M.

This amount every two hours during the day.

No other medication is needed, though the joint may be painted with tincture of iodine.

INFANTILE COLIC.

Instead of treating these cases with opiates, Dr. J. P. F. Brunner recommends, in the *Pacific Medical Journal*, the following combination, which he finds gives almost instantaneous relief and effects a permanent cure:—

℞.	Tincturæ assafetidæ,	gtt.xv	
	Tincturæ cinnamomi,	℥ ss	
	Sodii bicarbonatis,	℥ j	
	Syrupi rhei aromat.,	℥ iij	
	Aquæ,	℥ iss.	M.

Sig.—Half a teaspoonful every three hours.

ACETATE OF LEAD IN DIARRHŒA.

In the London *Medical Times and Gazette*, Dr. B. Nicholson recommends, in ordinary diarrhœa and such as precedes dysentery, the following, which he finds almost universally successful:—

℞.	Plumbi acetatis,	gr.iv	
	Pulveris opii,	gr.¼.	M.

For one dose, thrice daily.

No good, but rather disadvantage, resulted from increasing the amount of opium, though the quarter of a grain was decidedly useful. As to the acetate of lead, it is convenient and portable, sedative as well as astringent.

ERGOT IN PHARYNGITIS.

In chronic pharyngitis, where the blood vessels of the pharynx are enlarged and tortuous, and the secretion moderate, Dr. Dabney reports (*American Journal of the Medical Sciences*) excellent results from the following:—

℞.	Ergotinæ,	gr.xx	
	Tinct. iodinii,	fl. ℥ j	
	Glycerinæ,	fl. ℥ j.	M.

Sig.—Apply to the pharynx freely, twice a day, with a camel's-hair brush.

A solution of Squibbs' solid extract of ergot also acts well in these cases, applied in the same manner.

Remedies in Tetanus.

In the last number of Schmidt's *Jahrbücher*, Dr. Knecht closes a long review of the recent treatment of tetanus. He finds that the plans adopted give the following result:—

By means of *surgical measures* (nerve stretching, excision, etc.), of 58 cases treated 28 died; mortality 48 per cent.

51 cases were treated with *curare*, of which 26 died; mortality 49 per cent.

60 cases were treated with *calabar bean*; of these 27 died; mortality 45 per cent.

134 cases were treated with *chloral* alone, of which 55 died; mortality, 41 per cent. To these add 23 cases treated by combining chloral either with bromide of potash, morphia, cannabis indica or belladonna, with only 4 deaths, and the mortality is 37 per cent.

63 cases treated in various other methods (bel-

ladonna, baths, jaborandi, opium, expectant method, etc.), gave 31 deaths; mortality 49 per cent.

From this exhaustive study he reaches the conclusion that *chloral*, especially in combination, should have the decided preference in the treatment of this formidable complication of wounds. Dr. Knecht refers to the case given in the MEDICAL AND SURGICAL REPORTER, vol. XXXVII, p. 268, as a good example of careful treatment.

Legal Objections to Cremation.

The medico-legal objections to cremation have been met by Dr. Trachini-Bonfanti, of Milan in an able paper. Dr. T. has been for 26 years the official medical expert of the criminal court of Milan; has in that period had charge of thousands of cases involving medico-legal questions; yet among them all only ten involved the exhumation of bodies, and four of these were in a case where the murderer had buried them himself, for concealment. This illustrates how slight is the oft-repeated objection to cremation that it destroys medico-legal evidence. It should be remembered that vegetable poisons can rarely be discovered after inhumation; while mineral ones are discoverable in the ashes.

Our countrymen will recall, in this relation, the example of Henry Laurens, of South Carolina, the first President of the Congress of the United States. He died at Charleston in 1783, and in his will directed his son to burn his body on the third day, as the sole condition of inheriting an estate of sixty thousand pounds sterling.

In Vino Veritas.

In the *Vierteljahrschrift für Gerichtliche Medicin*, July, Dr. Westphal reports the case of a murderer who was alleged to be partially insane. Among the tests was the administration, on two occasions, of sufficient brandy to make him quite drunk. In this condition of intoxication he plied him with a number of questions, believing that if his delusions were simulated he could not keep up the deceit when so much in liquor. As the man still persisted in his insane statements, the expert concluded that he was really demented.

A Sanitary Puzzle.

One would suppose that a race who live out doors, in a pure, dry air; who are temperate in all things, never touching distilled or fermented liquors; who are moderate in passions, simple in life, and cleanly in habits; would be blessed with length of days. The Bedouin tribes of the Euphrates are such a race. But, according to Lady Anne Blunt's recent book of travels, in spite of their absolute temperance and constant open air life, they decay prematurely. Well made and handsome in youth, at forty their beards are gray; at fifty they are old; and the age of sixty is reached by few.

CORRESPONDENCE.

FOREIGN.

Letter from London.

ED. MED. AND SURG. REPORTER:—

During a pleasant call upon Dr. Hughlings Jackson, he kindly invited me to visit his wards in the London Hospital with him. This, of course, gave me an opportunity to see very many cases of nervous diseases of all sorts. The Doctor is in hopes that something yet will be found as a more radical mode of treatment for epilepsy. As yet, he says, it is rather discouraging, but the problem must be worked at as it is presented to us, and for various reasons he feels quite sure the future will be brighter for the poor epileptic. His experience with the bromides, as regards producing an eruption, is that only in exceptional cases is such an unpleasant feature present, and when such does come it is quite well controlled by the use of arsenic.

If I mistake not, our Dr. Mitchell says the same, that the bromides produce eruptions only occasionally.

My own limited experience has been just the reverse. It may be all the exceptional cases happened to me. At any rate, the acne of bromism has been a bother to me in several cases where it was necessary to push the remedy.

The English physicians love theory, and it was quite amusing, and indeed not without interest, to hear a doctor from Manchester, of some local repute, discussing with Dr. Jackson, as we all went the rounds, the "*localization*" and the "*tracts*," and the "*ganglia*." It were well for a medical man to be fresh from the hands of a *Pancoast* or a *Leidy* before venturing to join in the discussion.

By the way, this same gentleman from Manchester had brought down to London, to show the Pathological Society, sections of the cord of patients dying of hydrophobia. He found certain tracts of the cord changed. Dr. Mackenzie feared these "changes" were simply the effect of staining. Dr. Jackson replied that the fact was valuable, even if the changes were *post-mortem* ones and the result of coloring, if each time *certain distinct tracts* were so affected. During this conversation, Dr. Jackson's character was nicely displayed. He is an unassuming man. To look at him, one would scarcely imagine the work so well known as connected with the name of Hughlings Jackson was done by him. Small in stature, pleasant in manner, with

a kindly smile, but none of that pompous, swelling style so often connected with men who know their names are a power, who are conscious of the great work done by them, and would ever remind those around them of it. During this talk about hydrophobia Dr. Jackson exclaimed, over and over again, "I trust you are right, Doctor, I trust you are right." That is, he is anxious to have the practice of medicine to be more sure, the relief to mankind more positive, especially of those diseases of the nervous system which so far seem to baffle all efforts made to cure or arrest them, and he cares not *who* adds a little here and a little there so only that it is done. He does not desire that each and every advance made in neurology shall be made by him alone.

The other cases seen were chorea, hemiplegia and muscular spasms. The treatment of chorea is about the same as by Weir Mitchell, in Philadelphia, concerning which I have written much within a year or two. The case of spasm was of the muscles of the left arm, occurring in a man who had a severe fall eight years ago, after which this gradually came on. It was a constant and very severe spasm of chiefly the flexor muscles, and was a most distressing sight. Treatment, so far, had accomplished very little. In reply to a question what had afforded him the most relief, the man said curare.

The doctor from Manchester (I am sorry to have forgotten his name), said in a few similar cases he has been able to find one certain spot in the spinal column if pressure is made upon which the spasms are controlled, and has had permanent pressure made over the spot. Again, he said, other spots if pressed upon seemed to make the spasms worse. C. C. V.

DOMESTIC.

A Case of Congenital Hydrocephalus.

ED. MED. AND SURG. REPORTER:—

On November 5th, 1878, I was called, at ten o'clock P.M., to visit Mrs. C., four miles in the country. On arriving I found a strong, healthy, well formed lady in labor with her fourth child; pains very weak and far between. I made per vaginam examination; found os well dilated and breech presenting. Gave one fluid drachm extract ergot at twelve o'clock. It did not encourage the pains much. At one o'clock A.M. gave one drachm more of ergot; this brought about violent ergotism.

The body and lower extremities were now born. Child living. At this moment all pains ceased. I could not succeed with the delivery. Believing that there was some malformation of the head, I sent for Dr. W. D. Craig, of Aledo, Mercer county, Ill., instruments and chloroform. Dr. Craig arrived at four A.M. Gave anæsthetic, and Dr. Craig with difficulty delivered the arms, but could not proceed any further with the delivery. Child now dead. The shoulders were drawn up so closely to the vulva of the mother that no examination could be made; labor pains having entirely ceased.

After further council we agreed to decapitate, which was done. The head now receded into the body of the uterus.

We now diagnosed our case to be one of hydrocephalus. Dr. Craig introduced the blunt hook into the mouth of the "dead head," and drawing it down into or against the pubic arch, gave it to me to hold while he, with a wrapped scalpel, made an opening in the left parietal bone of the cranium, when a gallon or more of fluid flowed, with small particles of brain. The skull now collapsed, and was delivered easily. I removed a large and healthy placenta. The patient had a good recovery, and said she felt better than after former confinements.

Can any of the correspondents of the MEDICAL AND SURGICAL REPORTER suggest any better plan of delivering a hydrocephalic baby than by decapitation? If so, please give us your suggestions through the MEDICAL AND SURGICAL REPORTER. GEO. IRVIN, M.D.

Aledo, Mercer Co., Ill.

NEWS AND MISCELLANY.

Two Prize Essays.

The German Empress has offered a prize of 2000 marks ($500.00) for the best essay on Diphtheria. The conditions are, that the writer is to bring forward important new facts as to the essential nature of the disease, especially with regard to the infectious matter which propagates it, its dissemination, and the means for arresting its progress. The essays may be written in German, English, or French, and must be sent to Prof. v. Langenbeck, Berlin, N. W. 3 Roonstrasse, on or before December 15, 1880.

The Pharmaceutical College of Madrid offers a prize of 5000 reals, ($250.00) to the author of the best memoir on the following subject:—

On a septic poison, with explanation of the method of isolation, and the experimental studies by which this is attained; with a demonstration of its nature, composition, properties and characteristics. A specimem of the poison is to accompany the monograph.

The competition will remain open until September 21, 1880, and competitors may be of any nation, but the memoir must be written in Spanish, French, or Latin.

New Medical Colleges.

Two "first announcements" of medical colleges reached us simultaneously the other day. One is that of "The Medical Department of the Arkansas Industrial University," at Little Rock. It is to have a voluntary graded three years' course, and in all respects to conform to the Articles of Confederation of American Medical Colleges agreed to at Atlanta. Attention is called to the fact that the General Assembly of the State of Arkansas passed an act legalizing dissection in 1873, and that subjects can be obtained without difficulty. The Secretary of the Faculty is Dr. R. G. Jennings, of Little Rock.

The second announcement is that of the "Homœopathic College of Physicians and Sur-

geons (Modern School)," Buffalo, N. Y. It seems the "modern school" of homeopathists intend to renounce what they call in this circular "infinitesimal and transcendental therapeutics," and give as big doses as they please. As the circular says—"the size of the dose has nothing whatever to do with therapeutics" (p. 6). It further adds: "An ounce of sulphate of magnesia in a case of diarrhœa is as homœopathic as a fractional part of a grain. Modern practitioners only claim for homœopathy that it is an addition to the old system of medical science, that it is simply a reform in the department of therapeutics, and that it begins where allopathy and all other schools end." As we have repeatedly shown, and as Hahnemann himself took pains to show, that the theory of *similia similibus* was constantly and largely practiced long before his birth, this last sentence is either a manifestation of gross ignorance or deliberate falsehood, we cannot tell which. But it is gratifying to see the follies of homœopathy recognized as such by its followers, and rejected one by one.

Some Pharmaceutical Novelties.

JAMES W. HORLICK & CO.'S PREPARATIONS.

We referred to these a few weeks ago. Since then we have employed their "Infant Food" and "Sugar of Malt" in several cases, including summer complaint of children, dyspepsia in adults and defective nutrition in phthisis. We have been much pleased with the results, and especially for infants, at this season of the year, we think their preparations most excellent. The firm has explained to us the method of manufacture, and it is well calculated to insure a permanent and valuable product.

GELATINE-COATED PILLS.

Some specimens of these pills, prepared by KEASBEY & MATTISON of this city, represent a high state of the pharmaceutical art. They resist the effects of moisture and temperature, are easy to swallow, and reliable in effect.

THYMOL CAPSULES; NITRO-GLYCERINE TABLETS.

We note these English preparations as desirable additions to pharmacy. Are they also made by American pharmacists? We do not know. The thymol is used in dyspepsia; gr.j in a capsule. The nitro-glycerine is valued in angina pectoris and sea sickness; one drop of a one per cent. solution in a chocolate tablet.

Sanitary Condition of Havana.

Dr. Chaillè, chairman of the Havana Commission, writes as follows, under date of July 18:—

As to the sanitary condition of Havana and of its harbor, it would be difficult to devise conditions more favorable to propagate disease. Built upon a thin layer of earth which covers extremely porous coral rocks, this foundation is deeply saturated with the excrements of many thousands of human beings and of animals, continuously deposited throughout a long series of years. Nothing can be worse or more offensive than the privy system of Havana. Associated with the evil hygienic conditions of the city, the harbor is, if possible, in even fouler condition.

This harbor, about one mile long, two-thirds of a mile wide, and some thirty feet deep in the deepest places, has a difference between its minimum low and its maximum high tide of less than two feet; and into this almost stagnant pond is daily poured the sewerage of the city, the offal of the slaughter houses, and the refuse from at least two large hospitals habitually infected with yellow fever and located on the very edge of the harbor. The fecal odor from this harbor is often distinctly perceptible.

Physicians in Foreign Countries.

American physicians who contemplate visiting Europe often desire to know under what regulations they can practice there. In France they will have to submit to an examination in the French language for "Officier de Santé," which is the lowest French medical qualification. In Belgium there is a similar examination demanded, after which the application to practice comes before a Board, which mostly refuses it. In Germany and Austria a foreigner may usually practice without hindrance, but he can take no legal standing as a physician unless he obtains a diploma from a German university. In Switzerland permission to practice can be obtained from the local officials, but it is revocable at their option. In Italy a diploma from a leading college will secure permission without difficulty. In Great Britain there are a number of licensing bodies from whom permits to practice can be obtained by submitting a diploma or passing an examination.

Animal Vaccination.

The use of animal virus is rapidly on the increase. A bill has been introduced into the British Parliament, with the object of procuring the vaccine lymph direct from calves. Under its provisions it will be compulsory on any public vaccinator, whenever the parents of a child shall demand to have it vaccinated with animal lymph, to have it so inoculated, and in case the demand be not complied with, no prosecution shall lie against the parents for refusing to have the operation performed otherwise.

Dr. Pissin, of Berlin, has published a report covering fourteen years of the progress of the "Institute for Animal Vaccination," in that city. It is full of valuable information on the subject. In the last four years the percentage of successes in primary vaccinations were 97 per cent.; in re-vaccinations 74 per cent.

A physician in Trier has lately had to pay a fine of 600 marks ($120.00) for inoculating a child with syphilis by means of a vaccine crust from another infant.

The Canal Boatmen.

We have learned since printing our editorial on pages 81, 82, that the sanitary supervision of canal boatmen does not come under the charge of the U. S. Marine Hospital Service, inasmuch as they pay no dues. It is a pity that they don't, as they would then be prevented from disseminating disease, as, from late English reports, it is very likely they now do.

Dr. Yandell on the Woman Question.

Dr. L. P. Yandell, in a letter from London to the Louisville *Medical News*, speaks thus on the woman question: and a good thing about the Dr. is that when he speaks he leaves no doubt as to what he means:—

"I have met two fine English women who have lately returned from their medical studies in France, and at an early day will take their degrees. I see no reason, barring human prejudice, why they should not succeed in the profession they have chosen. Having strong minds, rare educations, high professional acquirements, fine presence, and all the ambition and energy that could be desired, what hinders them? For my part, I am strongly inclined to allow—nay, I am in favor of allowing—the fillies an equal chance with the colts in the race for the medical cup and purse."

Personal.

—Dr. Brücke, Professor of Physiology, has been elected Rector Magnificus of the University of Vienna. He is the first Rector since the foundation of the University who has not been a Roman Catholic. He is a Protestant.

—Two young sons of Dr. A. H. Boyd, in Livingston county, Ky., being ill, their father determined to give them santonine, but through mistake gave them some poison. In half an hour they had spasms, and one died in half and the other in three-quarters of an hour. The santonine will be analyzed.

—The death is announced, of Mr. Charles F. Maunder, F.R.C.S., a distinguished London surgeon, at the early age of forty-seven. Overwork and financial losses led to an affection of the brain, and in an attack of aberration he committed suicide. He was author of an "Operative Surgery," a "Surgery of the Arteries," and other works.

—There is a movement on foot in the Georgia Legislature to procure the selection of the late Dr. Crawford W. Long, of Athens, as one of the two prominent men of the State whose statues are to be placed in the National Gallery of the Washington Capital. As the discoverer of anæsthesia, the Atlanta *Constitution* says that Georgia never produced a man whose labors entitle him to greater recognition or more enduring fame.

Items.

—The Select Committee of the House of Commons on the Coroner's (England) Bill has determined to recommend that in future medical men shall be disqualified from holding the office of coroner.

—A disease of the digestive system is ravaging Centre Point, Lynn county, Iowa. Fully twenty persons have died from its effects during the last thirteen days of July, and an equal number have been prostrated by it. It is also raging in Walker, a little town seven miles from Centre Point, several deaths have occurred there. By some it is said to be epidemic dysentery.

OBITUARY NOTICES.

—Dr. John Vincent Morgan, who died recently in Newburgh, was a young man of great promise. He studied in Berlin, Paris and Vienna, and practiced in New York.

—Killed by lightning, on the evening of July 16th, 1879, Dr. Lucian Melville Sykes, of Muldon, Mississippi. Dr. Sykes was a prominent physician in his county, a member of the Monroe County Medical Society and the Mississippi State Medical Association. The latter delegated him, last April, to the American Medical Association, at the meeting held in Atlanta, Ga.

—Of recent deaths among foreign medical men may be mentioned that of M. Faivre, Professor of Botany at the Faculty of Sciences, at Lyons; Dr. Jacquemier, an eminent obstetrician of Paris; Dr. Campbell, another Parisian obstetrician well known in the "American colony."

QUERIES AND REPLIES.

Dr. D. presents this case:—Dr. A. is a regular physician. Dr. Z., a homœopath. At the solicitation of Dr. Z. Dr. A. accompanied Dr. Z. to see a patient of his (Dr. Z's), and prescribed for said patient. Has not Dr. A. violated the code of Ethics?

ANS.—He certainly has. The following is an extract from the English *Code of Medical Ethics*, edited by Dr. Styrap:—

"For a legitimate or orthodox practitioner to meet a professor of homœopathy in consultation, is a dishonest and a degrading act—dishonest, because he lends his countenance to that which he knows to be a dangerous fallacy; and degrading, inasmuch as he has neither the manly professional honesty to resist the temptation of a possibly liberal fee, nor the moral courage to discountenance the capricious vagaries of a patient."

Talis. Propylamin, or more correctly trimethylamin, was fully tried in acute rheumatism as much as twenty-five years ago; but in spite of all that has been said in its favor, somehow it has gained no permanent foothold. The chloride sells at about $7.00 per oz.

Dr. I. K., of Ill. We have heard of dandelion root coffee being used, but that taraxacum in this shape has any "deobstruent" or other effect on the liver, we doubt.

Dr. Elmore. There is a biographical sketch of Dr. Benj. Church in Thacher's *Medical Biographies.* He was something of a poet and more of a Tory.

Azure. If anything further was wanted to show the folly of the "blue glass mania," it is given in the recent demonstration of Dr. Draper, that there are no "heat rays" or "chemical rays" in the spectrum, but that all the rays have equal calorific and chemical powers.

MARRIAGES.

BANNING—LOCKWOOD.—July 23, at Mount Vernon, N. Y., by the Rev. Stephen F. Holmes, Rector Trinity Church, Archibald T. Banning, M.D., and Jessie T., daughter of John A. Lockwood.

DEATHS.

HARRIS.—In Memphis, Tenn., July 20th, of yellow fever, Dr. J. C. Harris.

MORGAN.—In New York, on Friday, 25th ult., John V. Morgan, M.D., son of the late Geo. Morgan, of New Orleans.

TAMAR INDIEN,

A laxative, refreshing, and medicated Fruit Lozenge, agreeable to take, and never causing irritation. Its physiological action assures the immediate relief and effectual cure of

CONSTIPATION, CEREBRAL CONGESTION, HEADACHE, INDIGESTION, BILE, HEMORRHOIDS, etc., etc., by augmenting the peristaltic movement of the intestines, without producing undue secretion of the liquids. Unlike pills and the usual purgatives, it does not predispose to intestinal sluggishness, and the same dose always produces the same effect, that is to say, never needs increasing. These properties render "Tamar" invaluable to the weak and debilitated, and especially to ladies previous and subsequent to their accouchement. It is recommended by the most eminent Physicians of Paris; notably Drs. BELIN and TARDIEU, who prescribe it constantly for the above complaints, and with most marked success.

Prepared by **E. GRILLON,** Pharmacien de lère classe, 27 Rue Rambuteau, Paris. To be had of all respectable Chemists throughout the world.

PEPTODYN.

The New Digestive is a combination of the whole of the Digestive Secretions—Pepsine, Pancreatine, Diastase, etc.,

Forming an invaluable remedy in the treatment of all forms of Dyspepsia, and diseases arising from imperfect nutrition.

N. B.—*The success of this Remedy has led to several imitations of it,* which consist largely of Milk Sugar, and, as compared with Peptodyn, are of little or no real value as digestive agents.

SAVORY & MOORE, 143 New Bond Street, London.

PARIS, 1867. Prize Medal.

BOUDAULT'S PEPSINE

IN POWDER, also WINE, ELIXIR, SYRUP, PILLS, AND LOZENGES OF PEPSINE.

Since the introduction of Pepsine by Boudault in 1854, **BOUDAULT'S PEPSINE HAS BEEN, AND IS STILL CONSIDERED, THE MOST RELIABLE,** as is attested by the awards it has received at the Exhibitions of 1867, 1868, 1872, 1873, and in 1876 at the Centennial Exposition in Philadelphia.

IT IS THE ONLY PEPSINE USED IN THE PARIS HOSPITALS.

Careful tests will enable any one to satisfy himself that **BOUDAULT'S PEPSINE HAS A DIGESTIVE POWER AT LEAST DOUBLE** that of the best Pepsines in the market, and that it is really the cheapest.

It is Sold in 1 ounce, 8 ounce, and 16 ounce Bottles.

Beware of **so-called French Pepsines** bearing fictitious names, and prescribe **Boudault's only.**

BLANCARD'S PILLS

OF UNCHANGEABLE IODIDE OF IRON.

Blancard's Pills of Iodide of Iron are so scrupulously prepared, and so well made, that none other have acquired a so well deserved favor among physicians and pharmaceutists. Each pill, containing one grain of proto-iodide of iron, is covered with finely pulverized iron, and covered with balsam of tolu. Dose, two to six pills a day. The genuine have a *reactive silver seal* attached to the lower part of the cork, and a green label on the wrapper, bearing the fac-simile of the signature of

Blancard

Pharmacien, No. 40 Rue Bonaparte, Paris.

without which none are genuine.

PHOSPHOROLE.

PHOSPHORUS and COD-LIVER OIL

have now an established position throughout the civilized world as important therapeutical agents. A *perfect combination* of the two has long been a desideratum, since they are both of value in the same disorders, while the cases in which one is demanded and the other contra-indicated are exceedingly rare.

The combination in PHOSPHOROLE has the twofold advantage of furnishing *the best possible form* for the administration of *phosphorus*, and *a more effective form* for the administration of *cod-liver oil.*

With regard to the former, it has been decided by the highest chemical and medical authorities that *phosphorus* should be administered *in a free state*, and in a vehicle which ensures its *perfect diffusion*, its *absolute unalterability*, and, as far as possible, its *prompt assimilation* without the gastric irritation to which the ordinary methods of exhibiting the agent give rise. It is well known that pills, emulsions, solutions in ether, chloroform, vegetable oils and resin, etc., have all failed to fulfill one or more of these conditions. Even an ordinary solution of phosphorus in cod-liver oil would not answer the purpose in all respects. We claim, however, that PHOSPHOROLE completely satisfies all the conditions. From the method of preparing it, in an atmosphere of dry carbonic acid, the phosphorus is *entirely dissolved without oxidation*, and by our mode of manipulation *a positive uniformity of strength* is ensured. It is then promptly bottled and sealed, and its *stability and permanence* thus secured. The exact amount of phosphorus in each dose is known, its efficiency is ensured, and the irritant effects upon the stomach are reduced to a minimum by the blandness of the oil. As a means then of administering *phosphorus* in the many cases in which it is indicated as a *nervous tonic and stimulant*, it is claimed that PHOSPHOROLE is the best attainable in the present state of our knowledge.

The value of *cod-liver oil* in phthisis is so familiar to the physician that it is needless to dwell upon it. But the value of *phosphorus* is also universally recognized in this disease, especially when complicated with nervous derangements. The *combination* of the two therefore furnishes a more effective form for the administration of cod-liver oil in the great majority of cases in which that remedy is indicated, and one which will at once commend itself to the profession.

A dose of two teaspoonfuls of PHOSPHOROLE contains $\frac{1}{100}$ of a grain of phosphorus. This dose, when given after a meal, is effective, and not very liable to interfere with digestion. *Phosphorus is cumulative in its action, and should be administered with watchful care.* About $\frac{1}{12}$ grain is considered the largest safe dose, and we rarely need go higher than $\frac{1}{20}$ or $\frac{1}{30}$ of a grain. At the very first appearance of the smallest gastric derangement, the exhibition of phosphorus should be stopped.

PHOSPHOROLE is handsomely put up in pint bottles only, and may be obtained at all first-class druggists throughout the United States.

SOLUBLE

Pills and Granules.

UNEQUALED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

1. The best materials are used in their manufacture.
2. No article required by a formula is omitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.

Our list of Pills and Granules embraces those made according to the formulæ of the U. S. Pharmacopœia; also most of those in common use among the profession.

HINTS IN THE OBSTETRIC PROCEDURE.

BY

WILLIAM B. ATKINSON, A.M., M.D.,

Lecturer on Diseases of Children, at the Jefferson Medical College; Physician to the Department of Obstetrics and Diseases of Women, Howard Hospital, Philad'a.

SECOND EDITION. ENTIRELY RE-WRITTEN AND ENLARGED. 12MO, CLOTH. PRICE, $1.00.

—o—

The very gratifying reception given this handbook of the essentials of the obstetrical art has led the author to submit it to a careful revision, and increase its size by adding a number of new topics.

It may safely be characterized as the most convenient, compact, reliable and handy *vade mecum* on obstetrics in the language; as the following personal and editorial statements sufficiently attest.

OPINIONS OF PHYSICIANS AND THE PRESS.

"It is really a '*multum in parvo*,' and will, I am sure, be of great service to multitudes in the profession who have hitherto followed the routine of old traditions."—*Prof. Fordyce Barker.*

"It is as good for the old as for the young practitioner."—*Dr. J. Marion Sims.*

"It abounds in extremely valuable hints, and is calculated to do much good."—*Prof. Goodell.*

"Founded upon the personal experience of the author, it must prove of value to the very wide circle of the profession who will be led to purchase it by their acquaintance with the author and his reputation."—(Philadelphia) *Medical Times.*

SOME SUGGESTIONS IN REFERENCE TO YELLOW FEVER.

BY GREENSVILLE DOWELL, M.D.,

Professor of Surgery in the Galveston Medical College, Author of "Yellow Fever and Malarial Diseases," etc.

[We have been furnished with a record of the recent observations of this experienced observer, from which we make the following extracts.—Ed. Reporter.]

* * * * * * * * *

The question is asked, when should yellow fever be declared epidemic in a town?

The rule in all epidemics is, when more deaths occur from one disease than from all others, in a given time.

But an exception to this rule might be made in yellow fever. And the answer I would give would be this: When there are two or more cases in two or more places, in any city or town, and a tendency to spread. I make this exception for the following reasons: That if persons wish to leave, they ought to leave before it spreads and infects them so they will carry it to other places. Again, to call special attention to these first cases, in order to completely isolate them and disinfect them, their rooms and clothing, that others may not take the disease. These first cases are usually called sporadic, and we are told sporadic cases never produce an epidemic. This is true! But we most positively assert there never was an epidemic without first starting in sporadic cases. Then, to prevent an epidemic, keep all cases isolated. Let no one go where they are but those who have had the disease, and let all houses be whitewashed with lime, clothes and other things washed in hot water. Send every one from the immediate neighborhood that has not been attacked. The Spanish doctors have a medicine which they give to all such, and others who are not sick, in an epidemic place: "Go quickly, go as far as you can, and come back late." Now, this is sound advice, and the only certain course for safety. I mean for those who have never had the disease, for I still assert no one ever has a real second attack, or if they do, it is only one case in two hundred. All the commissions sent out to investigate this subject, from Louis to the present time, and two-thirds of all authors that have written upon it, assert this to be a fact. So no one need to fear the disease who has had a genuine attack. But it will not do to take every doctor's diagnosis, for they often make mistakes; many of them make no distinction between yellow fever and periodic fevers, or believe yellow fever to be only an aggravated form of miasmatic (periodic) fever. There have been quite a number of such, and a few are still left, but their number is lessening every day.

Another question of great importance is, how to manage an epidemic?

First, all should leave who can. Go quick! do not fall over one another, but be calm; go as gentlemen, and not as sheep. Take as little with you as possible, for you may carry the disease with you. If you cannot go far, go to the nearest place that is high and dry and with plenty of water, and where your supplies can be sent you in an open space, and only brought by those who

have been known to have had the disease. Do not go back in the daytime or especially at night, for it is not safe either night or day. Let no one come and stay with you from the infected districts. Be quiet; it will not come to you if it is not brought. Live in tents, not in houses, and if brought you will not take it, even sleeping in the same bed; but this I would not recommend any one to try, if it be possible to avoid it. If these instructions are fully carried out, you may stay within one mile of an infected place without danger.

Those who cannot or will not go away should live soberly and temperately. Never commit any excesses in eating, drinking, or doing anything that will exhaust mind or body. If you have been a hard drinker, let up; never get drunk, by no means, or at any time. It would be well to close all saloons. Form a Howard Association, and give full power to them to manage everything. The Howards should first prevent all persons from coming into the infected place except citizens, whether nurses or doctors, or any other persons, for they cannot do much good, and often do great harm, by adding to the number to be treated and taken care of. All doctors, ministers and apothecaries of the place should remain; it is their duty and they should no more desert their post than a sentinel on duty.

Call for doctors, nurses, ministers and apothecaries that have had the disease, until you get as many as are required. Hold no public assemblies of any kind, for we have instances of great outbreaks and rapid spreading of the disorder from these causes.

Do not burn bedding or clothes in open places, for it is believed that this is a frequent cause of its rapid spreading, and besides, hot water is better than fire. Dr. Rush tells us that the fires built in the streets were generally believed to have made the disease worse, and the burning of bedding in the streets of Memphis, in 1878, was undoubtedly injurious, and most certainly did no good, but caused many to suffer for bedding and clothing when cold weather came. So we do not recommend clothing or bedding to be burned; at least, *never in the open air*. Lime freely sprinkled in the streets after a rain, in alleys and low places, has done much good in Galveston, Texas, but this ought to be repeated after each rain. Chloride of zinc solution should be freely used on floors, in chambers, and on streets. All vomitings and stools should be saturated with it, and removed from the room and buried or destroyed by hot water. Only one patient ought to be allowed in one room, large or small, and the bed put in the centre of the room, free from all draughts, but with plenty of fresh air. No one ought to be removed after he has once taken off his clothes, if he is at all comfortable. I am much opposed to hospitals for yellow fever patients, as I believe the cases are always worse where one has died; many patients make so much noise that they ought to be where one could not see or hear another. On the score of economy, hospitals are a great saving of expense, for a patient can be treated for one-quarter of what it will cost to treat him alone. Nurses and doctors ought not to talk about other cases in the presence of one sick with yellow fever. There should be no tolling of bells. Only doctors and nurses should be admitted to the room, unless friends are specially called for. Two nurses, one for night and one for day, ought to be provided. One of them should always be in the room, let the patient's situation be what it may, for they may get up or do something that will cause a fatal result in only a few minutes.

Medicine ought to be prepared in proper packages, according to well recognized prescriptions, so it could be given promptly.

CLINICAL STUDIES OF INEBRIETY—EARLY SYMPTOMS.

BY T. D. CROTHERS, M.D.,
Supt. of Walnut Hill, Hartford, Conn.

The curability of inebriety depends (as in other diseases) on its early recognition and treatment.

The common inquiry, how many can be cured, can never be satisfactorily answered until this disorder can be treated in the early stages.

Many physicians who have never studied these cases doubt an early pathological stage, and never recognize a disease element until inebriety has gone on for years, and then give great attention to the dividing lines between vice and disease, and seek in this way to measure out the treatment by the condition of responsibility which may be present. The absurdity of such views are apparent in the history of every case. A very able physician sent his son to our asylum for this disorder, with a long statement of the case, caused, as he supposed, by vicious company, and only pathological so far as alcohol had diseased the organism. He had made a study of the case, and was convinced it was the result of surroundings which, after a few weeks' residence in the asylum, would call for moral treatment almost exclusively.

From his mother and other sources the follow-

ing history was elicited: His grandfather on his mother's side was drunken. His grandmother and two aunts on his father's side were monomaniacs, and finally became demented. From two years old and upward he had exhibited a most impulsive, irregular appetite. On many occasions he had both eaten and drank to surfeit and great illness. He always ate exclusively of such foods as he liked, for days living on potatoes or bread alone, then changing to soups or liquids. He was very changeable, and never angry unless his desire for foods or drinks was opposed. He drank cider to intoxication several times, when in the country. As a student he was fitful and impulsive, at one time excelling in some particular study, then showing great indifference or stupidity. His greatest pleasure seemed to be in the table, and the odors of certain drugs and perfumes. At fourteen he became very licentious, and was sent away to a private school. At eighteen he drank beer every day, and associated with low characters. At twenty he was sent to the asylum, a chronic inebriate. He was much debilitated in both body and mind, and filled with low thoughts and impulses. His father dated all his troubles to the drinking of beer in bad company. No one had traced any hints, in his early history, of the approach of inebriety. He was born with a marked predisposition to this disorder, and sooner or later, under ordinary circumstances, it would have developed. All the early symptoms were marked, and had a pathological significance, as much so as the trembling and incoördination from alcohol.

There are probably no cases of inebriety inherited, or with a predisposition to this disorder, which do not give more or less prominent early symptoms, that may be noted. These symptoms vary, as in all other nervous and psychical disorders, and because they are rarely ever noted in the early stages, are doubted.

The two following cases have been studied carefully, and will be found to represent some of the many early symptoms of nearly every case of inebriety. When these early symptoms shall be practically recognized and acted upon we shall be able to prevent and successfully treat many of these most deplorable cases, which are at present not only incurable, but a pest and disgrace to every effort made in their behalf.

Case 1.—Inebriety Preceded by Conditions of Nerve Exhaustion and Morbid Impulses to Eat and Drink, and General Dietetic Irregularities.

B. Father a physician and confirmed opium eater; mother a nervous invalid; all his brothers and sisters died during childhood. When he was three years old he exhibited violent anger, and was prostrated with fever from the effects of the excitement. A strange, impulsive temper was manifest, which grew rapidly from this time, and was always provoked when refused any article of food or drink which he craved. He seemed different from other children, in having only one source of gratification, this was food and drink. On all other matters he was quite indifferent, but when opposed in the gratification of his appetites his anger was furious and maniacal. So severe were these paroxysms, that his friends studied to avoid them by indulging every desire. He always suffered from fever and great prostration for a day or more after a paroxysm of anger.

At ten years of age he was thin, tall, and very nervous, fond of all kind of sports, rarely angry, usually generous and of mild disposition in all things except at the table and when hungry, when he would exhibit the greatest selfishness and irritability. At this time he showed a great liking for burned food and bitter drinks; wormwood and horse radish, ginger, pepper, with other condiments, were great favorites. He would complain of great weakness and want to remain in bed, have some fever and drink large quantities of water, be reticent, and after a few hours recover his usual vigor. At such times prominent symptoms of acute diseases would come on and disappear in a few hours. In school his mind was active, but his memory was defective, and he seemed to lack power of coördination, and could not apply his mind when he wished, to any study or work.

At fifteen years of age he went to a boarding school, and was first noticed to drink beer. He exhibited great fondness for it and extreme cunning in procuring and secreting it from his playmates. His general health was better, and he was less often angry and prostrated after; but at times complained of headache and inability to sleep. Then he would be heavy and stupid for several days, dropping into sleep whenever alone and when the surroundings were quiet.

A year later he was converted, and became deeply religious, and began a course of study for a clergyman. Here the same uncertainty was manifest in the changing character of his studies, pursuing one branch for a time, then changing to another, without sufficient reason or cause.

The death of his father at this time prostrated him for many weeks with a low nervous fever, for which he was given wine, with good results.

He recovered with a conviction that he needed richer food, also that he never could expect long life unless he gave great attention to this matter.

At eighteen he gave up study and became a bookkeeper; he was heavy, stupid and dull in his manner and work, was also notional and irregular, some days working very hard, and then relaxing. He lived on the richest food that his means would allow, and drank beer, ice water, tea and coffee, in large quantities. He perspired very freely, and complained often of great exhaustion. He affirmed that he was unable to go on with his studies, owing to general weakness, which he hoped to overcome by rich, building-up food. During one of these paroxysms of nervous exhaustion he came under the care of a quack, who urged brandy as a medicine. The result was a rapid relief of all his old depression and stupor; he was a new man, filled with hope and ambition never felt before. After a time he drank to intoxication, and then he lost all ambition, and a change of habits, manners and disposition came over him, rapidly going from bad to worse, until at twenty-one he was brought to the asylum an inebriate. He was a constant drinker, suffering from hallucinations, muscular tremblings and general congestion. He recovered partially, went out, relapsed, and died from embolism, probably.

In this case two prominent symptoms pointed conclusively to inebriety, viz., the extreme impulses for food and drink, with ungoverned control, and prostration, which seemed to follow every excess and nerve agitation. In these paroxysms of nerve prostration alone are hints of an inebriate diathesis which will find in alcohol a relief, and use it ever after, under all conditions and circumstances. The early dietetic morbid impulses also indicated a want of balance and control of this function, which alcohol would sooner or later be found to relieve, as opium does pain, and while relieving it produces a pathological condition which ever after demands it.

Case 2.—Inebriety Manifest in Early Life by a Taste for Tea, Coffee, and Strange Kinds of Food and Drink, Associated with Emotional Irregular Brain and Nerve Power.

H. Father a speculator, and nervous, excitable man. Mother a nervous invalid for years, and died in his infancy. He was brought up by a rich aunt, who gratified his every whim. When five years old the family physician noted that he was very impulsive in his appetites, eating to surfeit, and suffering from severe attacks of indigestion, very often. He would secrete bottles of wine, and drink to stupor whenever he could. Unless he was guarded closely he would use only one kind of food and drink, until he grew sick of it. Nearly every month the physician would be called to prescribe for indigestion and general nervous fever, the result of overeating. Tea and coffee he drank at all times, and with great apparent satisfaction. He was always wanting to taste foods and fluids, and seemed to have a keen sense of the differences from taste. When visiting a drug store, he would delight the clerks by his great willingness to taste all kinds of fluids and solids. He grew up rapidly, and was very emotional and sensitive, rarely taking offence, but sympathizing with every one who was in trouble. He was very fond of excitement, and was depressed when alone, and frequently in tears when the day was stormy and he could not go out. He wanted to be in the centre of excitement and noise, and when sent to school cared more for play than books. As he grew older the attacks of indigestion became less frequent, but his appetite was more capricious, craving coarse foods and bitter, pungent condiments, and also was exceedingly changeable. As a student, he was likewise uncertain, full of changing emotions, and either very active or stupid, in both perception and memory. In his habits he was irregular, setting up all night to finish a novel, and depriving himself of many comforts, or making great exertions to procure certain articles of food or drink, or living in the most mechanical way, going to bed at a certain time, and getting up at a designated moment, performing every duty with precision, etc. At times he was buoyant and overflowing with joyous conceptions, then depressed and gloomy. All these irregularities grew more and more prominent as he developed into manhood. He was called eccentric by his intimate friends. At college he was noted for his poetic talents and love for rich dinners. He would live for weeks on the coarsest diet, then indulge in a round of the richest dinners, with wine and beer, not unfrequently becoming intoxicated. When twenty-one, he went to travel in Europe, and after two years returned an enthusiastic art student, and a drinker of wine. Two years later he drank to intoxication every day, and was brought to the asylum a paroxysmal inebriate. He would drink two or more glasses of brandy for weeks, then drink hard and to constant stupor for many days. He was feeble in both body and mind, and had but one desire, and that was to drink and get relief from what he claimed was a burning in his stomach. He recovered slowly at

the asylum, and is now back on a farm, temperate, but unfit to guide or take care of himself.

These cases were clearly of defective brain and nerve organization, from inheritance. The disorders of taste and will power were symptoms of this disorder, or distinct physiological hints of the growth of a diseased condition, which, with more or less certainty, would terminate in inebriety.

Alcohol at any time would explode this condition, giving form and shape to the diseased tendencies, increasing the degeneration, and developing a physical and psychical neurosis, which follows a regular line of march, to death.

These cases are typical, and include the symptoms of a large number that are going down regularly every year, unobserved. The profession generally do not recognize any symptoms before a condition of continuous intoxication, and this is called vice or accidental disorder, which may become disease.

Such views, so utterly at variance with the clinical facts, which may be verified in the observation of nearly every physician, are a source of infinite mischief, by precipitating thousands who would and should be recognized as having disease, and be restored, or, at least, be placed in conditions from which the possibility of recovery would be great.

In a recapitulation of some of the more prominent symptoms which mark this early stage of inebriety, the following may be mentioned:—

Impulsive and unregulated tastes for foods and drinks, morbid selfishness and changeableness of plans and purposes, great irritability and sensitiveness, emotional disturbances, conditions of depression and exhaustion, insomnia, and always neurasthenia; this, with a nervous temperament and weak will power, are present in nearly ever case long before they become inebriates. These symptoms are not always followed by inebriety, but they precede it, bringing the victim down to the border line, where, with the slightest exciting cause, he will become an inebriate at once. Persons with these conditions are continually haunted by the shadow which always forecasts the storm that may break at any moment.

—Dr. Chaillé, who is now on the Commission sent to Havana by the National Board of Health, has brought forward a number of facts to prove the great need of a competent medical officer in connection with the consular office at that port, authorized to telegraph promptly the departure of infected vessels, and to discharge other important duties.

A CASE OF ATROPHY OF THE OPTIC NERVES—RECOVERY.

BY J. A. LIPPINCOTT, M.D.,
Of Pittsburg, Pa.

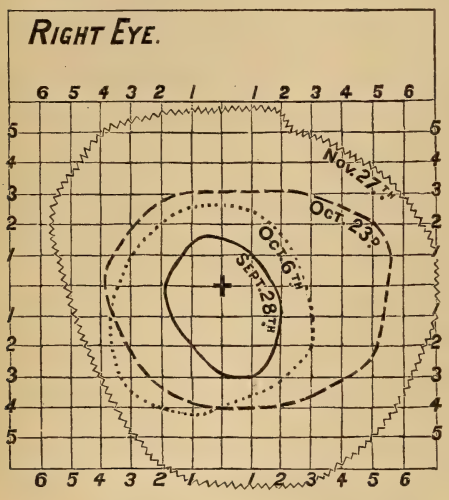
In ophthalmology, as in other departments of medicine, while diagnosis has in recent years made immense strides, therapeusis has not advanced correspondingly. Although a tyro in ophthalmology can distinguish well marked atrophy of the optic discs, and unfortunately finds abundant opportunities of exercising his diagnostic powers, very few cases of anything like complete recovery from this disease have been published; a fact which is in itself sufficient to justify the following report:—

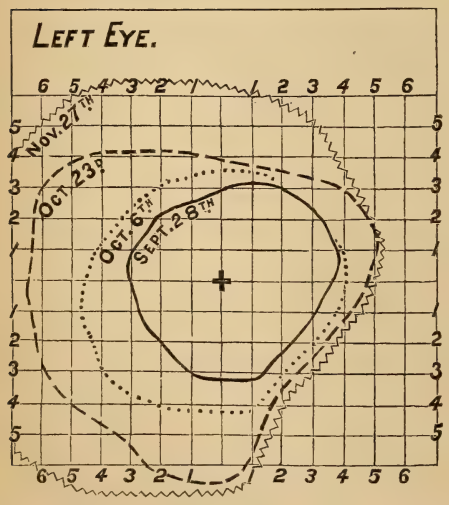
John Steinbach, aged 54 years, a policeman, of German birth, who had for many years been addicted to the moderate use of tobacco and the excessive use of whisky, was seized nine months before consulting me, with what, from his description and the statement of his physician, appears to have been an attack of *mania a potu.* On his recovery, vision for both near and distant objects was somewhat blurred, and there were slight photophobia and epiphora. Finding that he could see much better at night than in daylight, he was in time transferred to the night force; but his sight continued to fail unintermittingly, and he was finally discharged.

When he made his first appearance at my office, Sept. 28th, 1877, his appetite was good, bowels regular, the urine perfectly normal, and with the exception of slight nervous insomnia, his general health was in all respects excellent. The pupils were of average size, and responded promptly to the stimulus of light. On ophthalmoscopic examination the optic papilla on the right side was markedly atrophied. It was of a bluish, pearly color. The capillary circulation seemed almost absent. The retinal vessels were very small, and the white lines on the arteries were clearly visible. On the left side the disc presented a similar appearance, except that the vessels were smaller, mere threads, but the bluish cast was not so pronounced. There was no cloudiness of the fundus in either eye. The sight had progressively diminished, so that now R. E. V. $= \frac{1\frac{1}{2}}{LXX}$ $(= \frac{1}{46}$ of normal), L. E. V. $= \frac{3\frac{1}{2}}{LXX}$ $(= \frac{1}{20})$. The visual fields of both eyes were very much contracted, that of the right being the more limited, corresponding with the greater impairment of vision in that eye. The perception of colors was very imperfect.

The patient, besides being advised to drink no more whisky, was at once placed upon strychniæ sulphat., gr. $\frac{1}{32}$, t.d.; and in order to leave nothing

undone from which the slightest benefit might be hoped, a three-cell galvanic current was applied twice a week, for five minutes at a time, on each side, the anode being placed on the back of the neck, and the cathode over the eyeball and temporal region. This treatment was continued for two months, during which the acuity of vision was tested from time to time, and repeated examinations made of the extent of the visual fields.





These last were made with the utmost care, the patient's eye being always exactly twelve inches from the blackboard, and every precaution being taken to ensure absolute accuracy. In the accompanying diagrams each small square represents a square on the blackboard, whose sides measured three inches. Thus the visual field of the right eye, taken September 28th, 1877, measured about 12x15 inches, while that of the left measured about 18x20 inches.

As will be seen by the diagrams, the fields subsequently taken progressively enlarge, so that by November 27th the field of vision in each eye was almost of normal size. The visual acuity also gradually increased, although not exactly *pari passu*, as shown by the subjoined notes.

Oct. 6th, 1877. R. E. V. $= \frac{3\frac{1}{12}}{LXX}$. L. E. V. $= \frac{5}{LXX}$

Oct. 8th. R. E. V. $= \frac{3\frac{1}{4}}{LXX}$. L. E. V. $= \frac{6}{LXX}$

Oct. 23d. R. E. V. $= \frac{3\frac{1}{12}}{LXX}$. L. E. V. $= \frac{6}{LXX}$

Reads small words in No. 14 Jaeger with his glasses, which measure + 2.5 dioptrics. Visual fields to-day decidedly enlarged, although vision of left eye is but little, and that of right eye none, better than it was October 6th.

Nov. 10th. R. E. V. $= \frac{4\frac{1}{6}}{LXX}$. L. E. V. $= \frac{6\frac{1}{8}}{LXX}$

November 13th. Patient complains of cramps in the legs. To take but one dose daily of the strychnia.

Nov. 15th. R. E. V. $= \frac{7\frac{1}{4}}{LXX}$. L. E. V. $= \frac{7\frac{1}{2}}{LXX}$

Can now distinguish the numbers on the houses, previously invisible. He can also tell the time on his watch, and can recognize people at a distance of three or four steps, whereas two months ago he "would pass his own daughter close without knowing her." He also states that he can now gaze at the sun for three or four minutes without the sight being affected, while previously he was unable to look at it for a moment without experiencing total (temporary) blindness. Before beginning treatment he could not see one lighted street lamp from another. Now he can see all the lamps "for a mile." To take the medicine thrice daily.

Nov. 20th. R. E. V. $= \frac{8\frac{1}{12}}{LXX}$. L. E. V. = do.

To increase the medicine to four doses daily.

Nov. 27th. R. E. V. $= \frac{8\frac{1}{2}}{LXX}$. L. E. V. = do.

The test letters are now recognized at the same distance by both eyes, but perception is rather more rapid in the right. Colors are distinguished moderately well. At this, as at previous periods, the ophthalmoscope revealed no decided change in the appearance of the optic papillæ. Patient was directed to take the strychnia at the rate of gr. $\frac{1}{10}$ daily for three weeks at a time, with intervals of one week, and to report at the end of two months.

Aug. 23d, 1878. The patient finding himself improving, did not return, as directed, but continued the medicine in the way above indicated for four or five months, when he discontinued it altogether, thinking himself well. At present his vision is $\frac{20}{XXX}$ in each eye, and he can read No.

2 of Jaeger with his glasses. The visual fields are of normal extent.

With the ophthalmoscope the retinal vessels are found to be somewhat larger than on his first appearance, though they are still far below the average size. The bluish tint of the discs is not so marked, and the capillary circulation seems reëstablished in places where at first no vessels could be seen.

June 29th. To-day, at my request, I received a visit from the patient, who presented the following condition :—

R. E. V. $= \frac{20}{xx}$; L. E. do. With his glasses he reads No. 1 of Jaeger slowly, and No. 2 without difficulty. Fields of vision normal. Color perception good. He states that he can see quite as well as he ever could. He has been for some months steadily employed, doing various kinds of work. He has taken during the past year—on his own prescription—three or four glasses of beer daily, and generally one of whisky in the morning, and he states that he feels perfectly well in every respect.

It is an interesting fact that the affection either began or became noticeable during an attack of mania a potu. It is altogether unlikely, however, that it would have been long delayed even if alcoholic delirium had not occurred at all. In this connection it may be remarked that the history of the case and the ophthalmoscopic examination indicated that the atrophy was probably pure or primary, and not consecutive to inflammatory swelling of the discs.

The irregular, jerky progress of the improvement in visual acuity will have been observed. Thus, in the first week both eyes, especially the right, improved markedly, whereas, in the following seventeen days the left improved somewhat, but the right not at all. In the next eighteen days the right made perceptible progress, but the left none. In the succeeding five days, during which toxic symptoms made their appearance, the improvement was decided, especially in the right, which was now almost equal to its fellow. In the following twelve days the right overtakes and slightly passes the left.

While the visual acuity improved *per saltum*, the visual fields steadily increased in area from the first. The only departure from this rule is in the field of the right eye for October 23d, which, as will be seen by glancing at the diagram, had contracted somewhat in its left lower portion, as compared with the field taken October 6th.

As to the remedy, strychnia undoubtedly offers more chances of success than any other agent, even in syphilitic cases, when active proliferative changes have long ceased. The beneficial effects of iodide of potassium, judging from my experience, will be conspicuous by their absence. It has been the custom with oculists to administer the strychnia by hypodermic injection in the temporal region. Though this is in all probability the best method, I considered it impracticable in the present instance, as the patient lived at a considerable distance, which latter fact also prevented me from prescribing the drug in increasing doses.

By reference to the notes made Nov. 13th and 15th it will be noticed that improvement was most rapid immediately after symptoms of strychnism manifested themselves. This has been observed before, notably in a case reported by Dr. G. C. Harlan, in the Philadelphia *Medical Times* for December 26, 1874.

It is improbable that galvanism is entitled to much, if any, of the credit, as the case progressed quite as favorably after its discontinuance as before, although I have seen cases in which it seemed to be of benefit.

In conclusion, it may be remarked that no importance was attributed to the influence of tobacco in bringing about the condition of the patient when he applied for relief; and he was, therefore, not advised to surrender what was to him a great solace. In point of fact, considering the complexity of the etiology of optic nerve atrophy, I am inclined to doubt, with Carter,* whether tobacco amaurosis is to be regarded as a condition proved beyond question. At any rate, the conclusion of Charles Martin,† who has attempted to draw a fine line of distinction between the symptoms of alcoholic and "nicotic" amblyopia, will scarcely be received without hesitation.

Hospital Reports.

PHILADELPHIA HOSPITAL.

SERVICE OF DR. E. E. MONTGOMERY.

Reported for the Medical and Surgical Reporter, by Joseph Martin, M.D., Interne.

Ovarian Tumor—Ovariotomy.

This woman comes before you with the following history :—

Mary W., aged 28 years, married, of irregular habits, entered this hospital April 23d, 1879.

She gives a family history of phthisis. She has never enjoyed good health. Began to menstruate at 12 years; was always regular, until four years ago. She has had three miscarriages; the first at five months.

Four years ago she noticed a swelling in the left inguinal region. This increased gradually, and during its growth her menses have occurred at irregular intervals. For the last two years she has had occasional retention of urine, necessitating the use of the catheter, and has always complained of morning sickness. She has suffered with pain in the back and lower portion of the abdomen, which has been frequently very severe; at one time it was so great as to cause her to attempt suicide, for which she was sent to the Insane department of this house. She is still very irritable, indulging in frequent quarrels with the other inmates of the ward, and at times requiring close watching to prevent self-destruction.

You will notice the prominent abdomen nearly symmetrically developed; the dark line from the umbilicus to the pubes; and that the breasts have darkened areolæ. These signs, with the history of morning sickness, would, I am sure, lead you to suspect this woman to be at the full term of pregnancy. Auscultating the abdomen, we find the fœtal sounds and placental souffle absent. A digital examination shows no vaginal roof stretching across; the uterus is freely movable, and apparently not enlarged. To satisfy myself still further, I introduce my finger into the rectum, and find I can isolate the uterus from the tumor, showing it not to be a normal pregnancy. The same examination excludes a fibroid or fibro-cystic tumor of the uterus. May it not, however, be an extra-uterine pregnancy? If so, we would be able, by introducing the finger into the rectum, beneath the tumor, to obtain the sensation of a solid body within, by ballottement.

Percussion over the abdomen shows a non-resonant tumor, and as I place one hand upon the abdomen and strike upon the opposite side, I can distinguish a distinct wave, by which I know the cavity contains fluid. You well know ascites would give this sign; but in ascites, as the patient lies upon her back, the intestines, filled with fluid, rise to the highest position, giving resonance upon percussion. This resonant zone changes with the change of position. Here, however, the central portion is dull, with resonance at either side, as if the intestines were pushed back.

A hydatid of the liver would grow from above downward, giving a border of resonance below.

A renal cyst would not be found so central; that it is not fatty, is shown by the presence of fluctuation. Having excluded these other forms we are quite certain we have to deal with an ovarian cyst. Projecting as it does to the left of the linea alba, with the history, makes it reasonable to suppose that it originated in the left ovary. You can see the freedom with which I move the abdominal walls over the tumor; that it moves up and down during respiration, and that I can greatly increase this motion by a little pressure, which leads me to conclude there are few if any adhesions. The clearness with which fluctuation can be felt from one side to the other indicates a single cyst.

Having satisfied ourselves that we have to deal with a single cyst of the left ovary, comparatively free from adhesions, what are we to do? That something should be done this woman's condition testifies; she has suffered from retention of urine at various times, until cystitis has arisen. The tumor is so great as largely to interfere with the functions of surrounding viscera, and our patient presents an expression of continual suffering.

The whole materia medica has been exhausted, without avail, in the treatment of these tumors. We can see how readily this would be true. We have here a sac lined with a secretory surface, but without power of absorption. The peritoneal cavity, on the contrary, has the power of keeping up the balance between secretion and absorption.

Paracentesis has been recommended and followed, with no permanent benefit; the sac again refills, and the patient is rapidly reduced by the great drain upon her vital forces. The operation is not free from danger, a large percentage of cases having died after first tapping. This is particularly true of multilocular cysts, where the contents are likely to be of an irritating character. The injection of iodine has been used, following paracentesis, but has become pretty well discontinued. I do not regard it justifiable, as we have a safer and surer method of dealing with these tumors, and where it fails to cure, it greatly increases the difficulty and danger in ultimate removal. The only justifiable plan of treatment in such a case is by ovariotomy, or the complete removal of the cyst. If the weather is favorable, I will at my next hour perform this operation before you.

May 21st. I come before you this morning for the purpose of performing an American operation; an operation that has immortalized the name of its originator, Ephraim McDowell; an operation that, when a published account was given, was universally decried by the civilized world, and by this city in particular. It was first performed in 1809, just seventy years ago, and the first account published ten years later. We now find it an established operation the world over, and this city has atoned for her former opposition by advancing a man who has done more than any other to give this operation an established place in surgery, and has performed it more frequently than any other American surgeon. I need hardly inform you that I refer to the late Dr. Washington L. Atlee. This operation has now become so popular that one operator alone has performed it over nine hundred times.

As to the proper time, all agree that it is better the patient should experience some inconvenience and suffering from the size of the tumor. This differs in individuals; one undergoing but little inconvenience from a very large tumor, while others, from pressure upon surrounding viscera, deranging the functions of the kidneys, alimentary canal, or bladder, or from mental anxiety in an easily excited individual, indicate the necessity for early interference.

In this patient, though the tumor is not excessively large, the pressure upon the bladder producing retention and subsequent cystitis, with her mental condition, are sufficient, in the opinion of myself and colleagues, to necessitate this operation. The result depends largely

upon the preparatory treatment. One great danger we have to fear is that of blood poisoning or septicæmia. This tendency we have endeavored to overcome by having the secretory functions in an active condition. The healthy action of the skin has been promoted by a nightly warm bath, the body thoroughly dried, rubbed with vaseline, and the patient covered up warm in bed. We have unloaded the alimentary canal by giving a dose of calomel, followed the next morning by castor oil, and finally, the day before the operation, by an injection, in the knee and elbow position, containing two drachms inspissated ox gall. In this way we have got rid of the scybalæ that have formed in the canal and been retained by the pressure of the tumor. It also empties the bowel of flatus, which would complicate the operation by the protrusion of the intestines, and is of so much annoyance after it. Her diet, while previously nourishing, has been for the last three days the milk porridge recommended by the late Dr. Peaslee. It consists of equal parts of milk and water, thickened with flour, boiled for an hour, and seasoned with salt. In this food we have but little waste and no foundation of flatus.

For the last three hours she has had no food excepting an injection of beef tea and whisky. We have endeavored to allay her nervous excitement by valerianate of ammonia, and to procure a sound sleep last night by a good dose of opium. I should have preferred a bright, clear day, but the postponement since last Saturday has had such an unpleasant mental effect, that I think it more judicious this morning to proceed with the operation. We have her dressed in flannel shirt and drawers, woolen stockings and ordinary night dress. The nurse has been directed to catheterize her just before she enters the room.

We will endeavor to carry out the antiseptic plan completely.

The object of the carbolic acid or thymol spray, as may be preferred, is to destroy any germinal material floating in the atmosphere, and thus prevent putrefactive change in the wound; even if we deny the germ theory of disease, there are none, I am sure, but will acknowledge that in this room, used as it has been during a number of years for clinical purposes, occupied as it is now by a large number of persons, the air must be largely impregnated with organic matter. This organic matter carbolic acid destroys, or so changes that its entrance into the wound is not attended with decomposition or fermentative changes. But do antiseptics produce this effect? Let results speak for themselves. Thomas, Emmet, Wells and Keith all agree that in this operation, without antiseptics, fever is the rule; with them, the exception. Atlee without saved 70 per cent.; Wells 78 per cent.; Keith 80 per cent. with them; Wells 90 per cent.; Keith 95 out of his last hundred, and in the last forty-one has not lost a single case.

With these results before us, if any one still doubts the efficacy of antiseptics, I can only say he would not believe though one were raised from the dead. The antiseptic plan implies the most scrupulous care and cleanliness. For this case I had this room sprinkled yesterday with a solution of carbolic acid (1 to 10). The room to which she will be conveyed after the operation is in the pavilion, and has been carefully cleansed, and a new mattress and bed clothes provided.

For the operation I have had prepared three solutions of the acid; 1st, in the proportion of 1 to 40, for the hands, dressings, and some linen cloths; this to be kept warm. 2d, 1 to 30, for the atomizer; and 3d, 1 to 20, for the instruments and sponges. The instruments have been placed in this solution for half an hour. The sponges were well freed of sand, washed in boiling water and soap, then in hot carbolic acid, placed in the sun for a few days, and finally placed in the present solution for the last three days. As an additional precaution, I have asked each of my assistants to follow my example in the careful use of the nail brush in washing his hands, and to anoint them with a solution of carbolic acid in olive oil, 1 to 10. To produce the spray, we have a modification of Lister's atomizer, which will keep up a spray for two hours. The dressings are, a protective, or piece of oiled silk, varnished upon one side, making it impervious to carbolic acid, antiseptic gauze, thin rubber cloth, antiseptic lint, and a flannel bandage.

Having the patient properly etherized, Dr. Montgomery, assisted by Drs. Walker, Warder, Hatfield, Bell, Heller and Martin, in the presence of two hundred students and physicians, proceeded to the operation. She was brought down to the end of the table, the feet hanging over upon a chair, the limbs tied together, and wrapped in a blanket, the abdomen bared, and a piece of oiled silk 3 by 4 feet, previously prepared by having an elliptical hole made in the centre, and the edge covered with emplastrum plumbi, was drawn down over it, leaving exposed only the part through which the incision was to be made, and completely protecting the clothing.

Beginning an inch and a half below the umbilicus, an incision three inches long was made, down to the aponeurosis, which was hooked up and divided upon a grooved director; no hemorrhage occurring, the peritoneum was divided in the same manner, to the extent of two inches, disclosing the pearly-tinted tumor. Upon exploring with the sound, and finding no adhesions, he enlarged the incision to five inches; the tumor was tapped with a Fitch trocar, and a gallon and a half of dark-colored fluid removed. The fluid drawn off, the sac was pulled out (no adhesions present), the clamp applied temporarily and the tumor removed.

When the intestines protruded they were covered and held back with some linen cloths wrung from the 1 to 40 solution, which had been kept warm.

The other ovary was now examined, and found to contain two small cysts, but it was thought best not to prejudice the result by its removal. The pedicle was secured by a carbolized silk ligature. A needle armed with a double thread was passed through the pedicle, the thread cut and each half tied separately, at first in a half knot, the clamp loosened, when, no bleeding occurring, the knots were completed,

the thread from one side carried around the whole pedicle and tied, the ends cut short, and the pedicle returned. All blood and oozing was now sponged out and the wound brought together by silver sutures, half an inch apart, introduced so as to include fully an inch of the peritoneal surface.

The wound closed, the dressing consisted of, 1st, the protective, or varnished oiled silk, two inches wide, the length of the wound, dipped in a 1 to 40 solution of carbolic acid; 2d, a single layer of antiseptic gauze, wet with the same solution; 3d, four layers of gauze, dry, covering the whole abdomen; 4th, a layer of thin rubber cloth, rubber side down; 5th, four layers of gauze; and finally the bandage.

The ether was suspended during the insertion of the last suture, and mustard plaster applied over the epigastrium, to prevent nausea. The patient was now carefully lifted upon a stretcher that had been kept heated, and carried to her room. The bed had been kept warm by placing along its centre some foot pans filled with hot water. These were lifted out, and the patient took their place. The operation, from the commencement of incision to the introduction of the last suture, occupied just thirty-two minutes, and was followed by no shock.

May 31st. I have the pleasure of again bringing this case before you, and will read the outline of convalescence, as prepared for me by the resident in charge, Dr. Martin. No shock followed the operation, but pulse and temperature kept good. Some nausea; vomiting prevented by application of mustard and sipping of hot water. Was very noisy and difficult to control, as she always has been after taking ether. She became so violent later in the day that it was all one person could do to keep her in bed, and I was obliged to give morphiæ sulph., gr. ss., hypodermically. The delirium still continuing, Dr. Montgomery ordered chloral hydrat., grs. xx, when she became quiet. She was given milk and lime water in small quantities at frequent intervals, and f. ℥ ij beef tea every four hours, by injection.

21st, 2 P.M. Temperature 98⅘°, pulse 84, respiration 28. 6 P.M. Temperature 100⅖°, pulse 100, respiration 22. Complained greatly of pain in the back, which was relieved by placing under it a pillow. Chloral was repeated at midnight, giving a very comfortable night.

22d, 10 A.M. Temperature 100°, pulse 120, respiration 24. Pain in the back much worse; would scream out at intervals of three or four minutes.

2 P.M. Temperature 101°, pulse 120, respiration 28. Tympanites marked; colicky pain over the abdomen. A soft rubber catheter was passed, per anum, allowing the flatus to pass and greatly increasing her comfort. Camphor, grs. v, chloroform, gtt. x, was given, in emulsion. The mental distress was so great toward evening as to oblige me to repeat the hypodermic.

6 P.M. Temperature 101⅗°, pulse 120, respiration 26. Skin and tongue dry; the latter with a brownish coat. Ordered—

℞. Morph. acetat., gr. j
Tr. digitalis, f. ℥ j
Spt. ether nit.,
Liq. ammon. acetat.,
Mist. potass. cit., āā f. ℥ ij. M.

Sig.—f. ℥ ss. every three hours.

Quiniæ sulph., grs. x, by injection. Complains of nausea after taking medicine or milk; relieved by the mustard. Chloral hydrat., grs. xxx, obtained a sound night's rest.

23d, 6 A.M. Temperature 101⅘°, pulse 120, respiration 24; feels much better; pain in back less severe; no tympanites. Fever mixture suspended, and tinct. digitalis, gtts. x, every three hours, substituted. Whisky, f. ℥ ss, added to each injection of beef tea. 6. P.M. Temperature 99⅕°, pulse 94, respiration 18. A small dose of chloral given, with good sleep.

24th, 6 A.M. Temperature 98⅗°, pulse 84, respiration 18. Feels well; tongue clean; skin moist; digitalis and whisky suspended. Menses appeared last night. Feels hungry. 6 P.M. Temperature 99⅕°, pulse 88, respiration 18.

25th, 6 A.M. Temperature 101°, pulse 120, respiration 28. Renewed digitalis; became quite violent in the afternoon; had to keep a constant watch to prevent her springing out of bed or disturbing the dressing. Gave chloral with elixir ammon. valer., producing sleep. 6 P.M. Temperature 100⅘°, pulse 92, respiration 20.

26th, 6 A.M. Temperature 98⅘°, pulse 86, respiration 18. Slept well and is in excellent spirits; talks rationally; digitalis suspended. 6 P.M. Temperature 99°, pulse 80, respiration 16.

27th, 6 A.M. Temperature 98⅕°, pulse 80, respiration 16. Had a quiet night without a hypnotic; condition good; allowed solid food. 6 P.M. Temperature 98°, pulse 88, respiration 18.

28th, 6 A.M. Temperature 99⅖°, pulse 84, respiration 16. More insane to-day than at any time since the operation; appetite, however, good; given chloral freely and morphia hypodermically. 6 P.M. Temperature 100⅘°, pulse 95.

29th, 6 A.M. Temperature 99⅕, pulse 84. Bowels moved by a free injection. 6 P.M. Temperature 99⅗°, pulse 84.

30th, morning. Temperature 98⅗°, pulse 84. Still noisy and violent. Evening. Temperature 100°, pulse 100. Gave quiniæ sulph., grs. x, by rectum.

31st. This morning temperature 99°, pulse 96. Feels quite comfortable.

This is the history of our patient's convalescence. It shows absence of shock, a moderate temperature record, and that the third, sixth and ninth days, which are usually regarded as critical, were passed over without an untoward symptom. It is with more than usual pleasure I bring her before you. This is the first successful ovariotomy ever performed in this hospital. Moreover, it is the first successful case performed in any public clinic in this city. I do not mention this with the desire you should impute the result to any superior skill displayed upon my part; for, in the cases to which I refer, the operation was performed by men of far greater skill and larger experience than myself. I do, however, believe, and wish to impress it forcibly upon your minds, that the result in this case was largely, if not altogether, due to the antiseptic precautions. I have been severely criticised for presuming to perform this operation before you,

and had I taken no greater precautions than in other cases operated upon in the clinics of this city I would feel that such criticism was well merited. The result in this case demonstrates, 1st, the possibility of performing this operation successfully in the presence of a large class, and within the precincts of a large hospital when proper precautions are observed. 2d. The value of the antiseptic plan, and when compared with previous cases, that its omission under such circumstances is unpardonable. In fact, my limited experience would cause me not to feel inclined toward its omission in any case, public or private. An auxiliary so efficient in hospital practice must necessarily tend to decrease the mortality in private cases, even though they be less exposed to septic influences.

June 23d, 1879. Her convalescence since last note has been continued and rapid; not an unpleasant symptom occurring to retard recovery. She is now able to go about the building and grounds; she feels better than she has for years, her only complaint being of a slight irritation about the bladder.

The Early Mercurial Treatment of Syphilis.

Dr. J. S. Hill, of Baltimore, writes to the Maryland *Medical Journal* (July)—

For several years past close observation upon the effect of small doses of protiod. hydrar., from the one-sixth to one-tenth of a grain, given two or three times a day, the diagnosis of syphilis having been established, has more and more inclined me to the conviction that if given when a true chancre is just beginning to show specific induration, it will almost surely put a stop to it. To see a chancre increase in hardness and size after its possessor has come slightly under the influence of mercury is one of the very rarest events.

If this treatment be perseveringly and intelligently followed up for months, or even a year or more, or so long as the natural history of syphilis would induce us to believe the secondary form of the disease should continue, then, as the time for the tertiary form approaches, discontinue the mercury and administer the iodide of potassium, in eight or ten grains three times daily, alternating the iodide of potassium with iodide of sodium, and continuing this course for seven or eight months, finally terminating the treatment by directing one-half ounce of cod-liver oil, and fifteen or twenty drops of syr. iodide of iron and manganese, given in combination after each meal, for three months; it will, when carried out with anything like an approach to regularity, not only throw disorder into the natural succession of the appearance of the eruptions and postpone their outbreak, but in a large majority of cases prevent them altogether, and in those cases where it fails to prevent them, invariably lighten their character and shorten their duration. One of the chief obstacles in the way of cure is the great difficulty we have in inducing a person who has no evidence of disease appreciable to himself, and who feels perfectly well, to persevere in so protracted a course, but this regularity having been secured, I have used this treatment each year more and more perseveringly, and have begun it as soon as the diagnosis could be considered certain. The result has been that, while formerly pursuing the expectant or repressive plan of treatment whenever the chancre was well indurated, I always expected constitutional symptoms in spite of treatment, I now regard their appearance with any degree of severity as quite exceptional. Each year of additional experience has made me more confident that this plan of treatment, if carefully and fully employed, is capable of procuring the complete extinction of the malady. The facts which we possess seem to warrant the opinion that it really destroys the virus; that it prevents its breeding in the blood, if that process has not already taken place, and if it has, cuts short its life in the tissues.

Treatment of Chronic Eczema, or Psoriasis of the Palm of the Hand.

On this subject Dr. Robert Liveing writes, in the *British Medical Journal*—

With regard to the treatment of chronic eczema rimosum of the palm, it is confessedly difficult. This arises from several different causes. 1. The position and mobility of the part affected is unfavorable to treatment; the hand is never at rest; the consequence is that, as fast as the skin heals it is rebroken by flexion and extension. This, of course, applies especially to the class of domestic servants and others who have to live by the use of their hands; for although they may be cured for a time, the cracked condition is very apt to return as soon as they resume their usual occupation. 2. The hands are the parts of the body most frequently washed, or perhaps kept constantly wet by particular occupations; this makes the cuticle brittle, and is very unfavorable to the cure of eczema rimosum. Barmen, for example, are particularly liable to this affection, favored, perhaps, by their mode of life, but excited by having their hands constantly wet with beer. The only way of dealing with them, after the eruption has been cured by rest and appropriate treatment, is to make them wear India-rubber gloves, which can now be obtained of any degree of thickness. I have permanently cured many obstinate cases in this way. 3. The most important element of difficulty is, however, the nature of the cuticle of the palm, which is very thick, and does not exfoliate readily; the consequence is that the eczema takes an unusual and abortive form;

the products of the inflammation do not escape, and the outer cuticle becomes thickened, brittle, dry and cracked. Instead of a free exit of fluid and rapid exfoliation, we have an almost horny condition to deal with; the principle of all successful treatment is to get rid of this (I am speaking only of the chronic form), and to promote a rapid removal of the hard, thickened, and imperfectly formed epidermis.

Acute or subacute eczema of the hand is best treated by the constant application of water dressing, lead lotions, or linimentum calcis, according to circumstances; the gist of the treatment being never to allow the dressing to get dry. Pretty free purging is generally indicated.

The ordinary chronic forms are well treated in the way Dr. Spender has pointed out, by the application of the lead ointment to which he refers. The compound lead ointment of the old London *Pharmacopœia*, made rather soft by the addition of oil, is also a good remedy; so, also, is Hebra's unguentum lithargyri; but in all cases the hand must be rested, covered, washed little, and the ointment constantly applied. It is well to bear in mind that the constant use of lead ointment stains the nails; this is not, however, of much importance.

I now come to those cases that are most obstinate: I mean where the cuticle is extremely hard, brittle, thick, and cracked across the natural flexures of the skin. In these extreme cases ointments produce no effect, and other means must be adopted to get rid of the outer cuticle, which entirely prevents any chance of cure. This is best done by the constant application, night and day, of a lotion of liquor potassæ (from two to four drachms of liquor potassæ to eight ounces of water is usually strong enough). The hand must be enveloped in rags kept constantly wet with the lotion, and covered with thin gutta percha, or something of the kind. This treatment must be continued until the cuticle is thoroughly white and macerated, when it will peel and rub off readily. The process may require to be repeated until the epidermis is reduced to its natural thickness and is thoroughly soft; the skin may then be treated with ointments and glycerine in the usual way.

Lastly, chronic eczema rimosum of the hand is one of the few forms of eczema in adults that is often benefited by the internal use of arsenic.

Poisoning from Carbolic Acid.

The *British Medical Journal* quotes Dr. Küster's recent study of this subject. The symptoms are classified in three different stages, according to the severity of the case. In the first stage, often the only symptom of poisoning is the change in the aspect of the urine. In the second stage, the digestion is impaired, the pupils move with difficulty, and the temperature is high. This last symptom is regarded by the author as being almost identical with the fever described by Volkmann under the name of aseptic fever. He explains chronic carbolic acid intoxication by supposing that large quantities of the drug, being repeatedly at short intervals introduced into the system, continually deprive the tissues of sulphuric acid by absorbing it, and thus impoverish them. The third and most severe stage of poisoning is characterized by the well known brain symptoms. Occasionally, muscular trembling and convulsions have also been observed in man, but only to a slight degree. The following conditions seem to predispose the system to carbolic acid intoxication: 1. Anæmia; 2. Septic and pyæmic fevers, and other weakening agents; 3. Infancy; 4. A peculiar individual idiosyncrasy; 5. The spot where the acid has been introduced into the organism. Husemann holds that it is most apt to produce poisoning when introduced into the circulation, less so, if given hypodermically, still less if given in the form of enemata, or rubbed into the skin, or applied to internal surfaces, and finally if inhaled. Sulphate of soda has often been recommended as an antidote to carbolic acid, but Dr. Küster has not found it to answer in severe cases. In order to avoid intoxication, he advises to wash out large cavities with an 8 per cent. solution of chloride of zinc, instead of carbolic acid. A 2 per cent. solution of the latter may, however, be used without danger for children and for operations in the abdominal cavity.

Salicylic Acid as an Anti-neuralgic.

Several cases of acute facial neuralgia and sciatica cured by salicylic acid, are reported by Dr. S. L. Abbot, in the Boston *Medical and Surgical Journal*, July, 1879. He adds:—

These cases seem to show that we have in salicylic acid and its compounds, as valuable a remedy in acute neuralgia as in acute rheumatism. Perhaps they indicate a closer affinity between these diseases than has been generally suspected. Two of the patients had had attacks of rheumatism. The cases, with the exception of the third case of sciatica, were all severe, and nothing could be more satisfactory than the very prompt and efficient relief which followed the exhibition of the remedy. In cases of a more chronic character my experience as yet does not justify me in expecting such complete relief by these remedies alone. A limited experience seems to show that such patients do not tolerate them so well, perhaps on account of the debility which is so marked a feature in these cases.

Rules for Operating on Epithelioma of the Cervix Uteri.

Dr. Marion Sims, in an article in the *American Journal of Obstetrics*, July, lays down the following rules:—

1. Do not amputate or slice off an epithelioma of the cervix uteri on a level with the vagina, whether by the écraseur or the electro-cautery.

2. Exsect the whole of the diseased tissue, even up to the os internum, if necessary.

3. Arrest the bleeding, when necessary, with a tampon of styptic iron or alum cotton-wool.

4. Be careful not to apply the tampon with such force as to lacerate the excavated cervix uteri.

5. When the styptic tampon is removed, cauterize the granulating cavity from which the disease was exsected with chloride of zinc, bromine,

sulphate of zinc, or some other manageable caustic capable of producing a slough.

6. After the removal of the caustic and the slough it produces, use carbolized warm-water vaginal douches daily till cicatrization is complete.

7. After the cure, put the patient on the use of arsenic, as a protection against the cancerous diathesis, and urge the importance of examination every two or three months, for the purpose of detecting the recurrence of disease.

8. Then, if fungous granulations or knobby protuberances not larger than a pea are found, lose no time in removing them; and treat the case afterward with caustic, just as in the first instance.

9. Almost every case may be benefited by operation, even when there is no hope of giving entire relief.

The Causation of Sleep.

The learned German alienist, Dr. Siemens, concludes that sleep is due to the activity of certain circumscribed parts of the brain, which form an inhibitory centre, and which are situated in the medulla oblongata, near to the convulsive centre. In support of this view, the connection between sleep and epilepsy is alleged. The inhibitory sleep centre stands in direct antagonism to the cerebral cortex; if the one is in a state of activity the other remains passive; the former can only exercise its function when the cortical substance is either inactive or nearly so. Sleep is much more easily induced in childhood, as the convolutions of the brain are at that time only partially developed. Sleep is also much more frequent and continuous when the cortical substance has degenerated, as in paralytic dementia; when its nutrition is faulty, as in anæmic conditions; also when it is to some extent paralyzed by the action of hypnotics or by excessive cold. On the other hand, no sleep can be obtained when the cortex is in a state of activity, due to strong psychic impressions, excesses, alcoholism, or any form of mental disease. When, owing to some morbid condition, sleep has been absent for a length of time, the products of fatigue must have been generated in the body in large quantities, but still the hyperactivity of the cortical substance prevails and prevents the occurrence of sleep.

Inhalation of Eucalyptus Oil.

Dr. Mosler, of Greifswald, in the *Berliner Klin. Wochenschrift*, No. 21, strongly recommends oil of the leaves of eucalyptus, administered by inhalation, as a remedy for pharyngeal diphtheria. The strongest dose which he has given was according to the following formula: oil of eucalyptus leaves, 5 *grams;* rectified spirit, 75 *grams;* distilled water, 170 *grams;* to be shaken together and used for ten inhalations. In this dose the medicine was inhaled four times daily, for ten or fifteen minutes each time, by a patient suffering from bronchitis and chronic laryngitis; it produced no troublesome effect, but acted as a powerful expectorant. Another formula employed by him was: oil of eucalyptus leaves, 2 *grams;* rectified spirit, 20 *grams;* distilled water, 180 *grams;* for ten inhalations. This was given with the best effect in a case of croupous pneumonia in the stage of defervescence, with residual infiltration of the right upper and middle lobes. It was inhaled four times, without any bad effect. A still weaker preparation (1:5 of eucalyptus oil, 15 of spirit of wine, and 200 of water) has been used by him in several cases of nasal and pharyngeal catarrh, and also in a case of pharyngitis accompanied by slight laryngitis, with good effect. Dr. Mosler is engaged in further researches on the action of inhalation of eucalyptus oil in affections of the respiratory organs.

The "Bilious Fever" of the South.

Dr. J. H. Miller, of South Carolina, writes to the Louisville *Medical News*—

From a close observation of the aggravated cases, I can attribute this disease to no other cause but the diet. On the plantations where I found the fever most frequent and of the worst type the laborers lived entirely, from the first of September to the first of November, upon home-made molasses. Now a few words upon the making of this food. The cane from which the juice is extracted is sometimes not permitted to ripen; the farmers, commencing on the crop so as to get through by frost, in many cases commence preparing it green. Then in the boiling process it is not prolonged sufficiently to cook the syrup thoroughly. I, therefore, consider the molasses made by the process enough to create this fever, or, at least, it will produce the excitant cause; and furthermore, the complications which generally arise from this diet tend to foreshadow a grave prognosis. Worms are bred in the system to an alarming extent, oftentimes in such amount as to cause total obstruction of the alimentary canal.

I will not burden this article with individual reports and different treatments, but only state that I wish every physician who practices in the country where these surroundings are to notice the cases and see if I am not right.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——In a reprint on Tuberculous Laryngitis, Dr. E. F. Ingalls, of Chicago, seems to think that such cases are not entirely hopeless as they occur in children. He gives a number of sound suggestions, which may all be summed up in the rubrics of the best of nourishment and hygienic precautions.

——A little book in 32mo, entitled, "Pocket Therapeutics and Dose Book," by Morse Stewart, Jr., M.D.; has been sent us by the publisher, Geo. D. Stewart, Detroit. It contains a poso-

logical table, incompatibles, formulæ, etc., and an Index of Diseases and Remedies, which latter we cannot believe would be of any value to any one legitimately holding a diploma. Price $1.00.

——Messrs. McKesson & Robbins' "Formula Book of Gelatine-coated Pills and Granules, Fluid Extracts," etc. (fifth edition), will be found handy and valuable to those who prescribe the excellent preparations of this manufacturing firm. Supplied gratis by the firm, New York City.

——An appreciative notice of Dr. Isaac Hays, by Samuel D. Gross, M.D., LL.D., has been reprinted from the *American Journal*, making a neat pamphlet of fourteen pages. Another and shorter notice of the life of the same eminent physician, by Dr. D. G. Brinton, has been reprinted from the Proceedings of the American Philosophical Society.

——The Chicago List of the Illinois State Register for 1879–80 has been received. It is published annually, under the supervision of the Chicago Medico-historical Society, with the coöperation of the Illinois State Medical Society. The editor is Dr. D. W. Graham. None but regular graduates in good standing are admitted to the list, and it is prefaced with a notice that violations of the Code of Ethics will lead to the omission of the perpetrator's name from future lists.

——The "Transactions of the State Medical Society of Arkansas, at its Fourth Annual Session" (Little Rock, 1879), makes a pamphlet of about one hundred pages. Besides the usual proceedings, it contains some interesting facts about yellow fever in Arkansas, by Dr. Linthicum; a "Study of the Etiology of Pneumonia," by Dr. J. S. Shibley; "Reports of Surgical Operations," by Dr. J. A. Dibbrell; "Remarks on Preventive Medicine," by Dr. E. Bentley; "Report of a Case of Resection," by Dr. R. G. Jennings; one of "Strangulated Hernia, with a Radical Cure," by Dr. E. T. Dale; and several obituary notices.

——An "Address on the Education of Girls," by Dr. Nathan Allen, of Lowell, Mass., urges the importance of more attention to the physical culture of the young female. He states that there are "unmistakable signs of physical degeneracy" in the girls of the present day. He says:—

"The registration and census reports are bringing to light startling facts in respect to decline in the birth rate, to the diminution of marriages, to the permanence of the family institution and changes in the population, etc. Should the same causes continue and increase, as they may, corresponding results will follow, and the next generation will witness in those matters still greater changes."

We have very little faith in the existence of any such degeneracy, and believe that its supposed evidence can be given a quite different interpretation; but at the same time, every one will agree that the physical culture of girls is a desirable and excellent thing.

BOOK NOTICES.

The Half-yearly Compendium of Medical Science. Edited by D. G. Brinton, M.D., 115 S. Seventh St., Philadelphia. Part XXIV, July, 1879.

A letter before us, from a Boston physician of eminence, reads: "I have the HALF-YEARLY COMPENDIUM from the first number, and there is more *cream* in it than in any other medical publication I know of. It is valuable because it instructs in the *little things* which the physician has to encounter in his daily labors." Such, indeed, has been the object of the various collaborators employed in the selections and translations which the volumes contain. Its range is as wide as medical literature; the present number, for instance, draws from not less than 77 medical periodicals, all issued within the first six months of this present year. Over *two hundred* different authors are quoted, and the abstracts are aimed to convey the pith and marrow of what they have written.

To readers of the REPORTER it is of interest to state that, by means of a carefully organized plan of working up the field of periodical literature, the contents of the COMPENDIUM are always different from those of the REPORTER; nothing appears in the one which is found in the other; and thus they are particularly adapted to be taken together.

The present number contains the Index of the Second Series, embracing the last twelve semi-annual volumes, each department being indexed by itself, so that the numbers can be taken apart and the departments bound into separate volumes.

Manual of the Principl s and Practice of Op rative Surgery. By Stephen Smith, A.M., M.D. Boston, Houghton, Osgood & Co., 1879. Cloth, 8vo, pp. 689.

This long announced book makes an extremely compact and complete volume. The type is small but clear, the matter well disposed and presented, and the text illustrated by 733 wood engravings, usually of small size, many of them

original. So many of the treatises on operative surgery have grown into bulky, dear and unwieldy tomes, that a manual, as this really is, will be welcomed warmly.

Of the manner in which the various subjects are treated little but praise can be said. In the earlier chapters the duties of the surgeon are discussed, and directions given how to examine and prepare the patients, manage hemorrhage, give anæsthetics, dress wounds, and watch the process of repair. In anæsthesia both chloroform and ether are recommended. Shock is spoken of as syncope and collapse; in both alcoholic stimulants are commended; nothing is said of coffee, belladonna or vinegar, and no distinction is drawn between primary and secondary shock. Under dressings, the antiseptic, the open and the hot water treatment are described, but nothing said about alcoholic dressings, Hewson's dry earth dressings, or Gamgee's plain dry dressings. Under plastic apparatus, starch, gypsum and silica splints are described, but Ahl's porous felt is omitted. The treatment of tetanus is given very superficially, the author saying that "nothing seems to check its progress or control its career." In the management of caries, Syme's excellent suggestion of blistering is not noticed; indeed, that most instructive author is very rarely quoted. In the details of operations, Dr. Smith is full, clear and accurate; and this portion of his work will be found to be the most satisfactory. His selection of operations is based on clinical experience, and will, we believe, be acknowledged by most surgeons to be judicious. Considering that the scope of his plan has enforced many omissions, his book will certainly have, and deserves, a favorable reception.

The Advantages and Accidents of Artificial Anæsthesia; a Manual of Anæsthetic Agents, and their Employment in the Treatment of Disease. By Laurence Turnbull, M.D., PH.G., etc. Second edition, revised and enlarged. With twenty-seven illustrations. Philadelphia, Lindsay & Blakiston, 1879.

Dr. Turnbull's Manual has met with a reception gratifying to him and merited by the care and labor he has bestowed upon it. The second edition comes out with a number of additions, which will make it more acceptable to readers. Of these we may mention various original experiments, especially with hydrobromic ether; additional rules for the employment of anæsthetics; a table of deaths from chloroform; description of a novel ether inhaler; a notice of the metric system; further information concerning the physiological and therapeutic action of anæsthetics in disease, etc. The supposed criminal uses of chloroform are discussed in the light of the most careful investigation, and shown to be greatly exaggerated in the popular mind. The various anæsthetics which have recently been studied by Dr. B. W. Richardson are described, and the investigations of the Committee of the British Medical Association are stated.

The manufacture of the book, the paper and printing, are not quite up to the average standard of Philadelphia publications, but the reader will excuse this, in view of the merit of the contents.

A Manual of Midwifery for Midwives and Medical Students. By Fancourt Barnes, M.D., London, etc. Philadelphia, H. C. Lea, 1879. 8vo, pp. 201.

Dr. Fancourt Barnes is the son of Dr. Robert Barnes, and has inherited his father's interest in obstetrics. The present volume, he tells us in his preface, "was designed more especially as one of reference for midwives," and therefore it does not discuss any of the obstetric operations, such as the application of the forceps, the vectis, craniotomy, version, etc. It concerns itself with pregnancy, the stages and mechanism of labor, presentation and position, hemorrhage, puerperal insanity and convulsions, etc. A series of examination questions proposed by the Obstetrical Society of London are added.

We hardly think this work was worth republishing in this country. It contains nothing not to be found in any of a dozen standard treatises; and omits so much, that medical students and practitioners will certainly be disappointed in buying it.

A Clinical Treatise on Diseases of the Nervous System. By M. Rosenthal. With a preface by Prof. Charcot. Translated by L. Putzel, M.D. N. Y., Wm. Wood & Co., 1879.

This is a volume of Wood's Library of Standard Medical Authors. Dr. Rosenthal teaches in diseases of the nervous system in Vienna, and his treatise, published about ten years ago, has been highly esteemed in Europe. More can be said in favor of his pathology and diagnosis than of his treatment. Little is said of the late additions to the therapeutics of such diseases, but much in favor of the hydropathic plan and electricity. The preface, by Prof. Charcot, was written for a French translation; in it he speaks well of the work, in spite of its German (although Austrian) parentage.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Half-Yearly Compendium of Med. Science,	**2.50**
Reporter and Compendium, - - -	**7.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**8.25**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

NATURE OF THE YELLOW FEVER POISON.

It is a candid and proper confession to make to the public, that the profession, up to the present time, has been unable to agree upon the nature of the yellow fever poison. Looking over the numerous articles which have appeared on the subject within the last year, one cannot but regret to see how discrepant are the views entertained by men of large experience.

There is, first, the party who declare it malarial, among whom we may mention Dr. J. C. Le HARDY, of Savannah, and Dr. J. G. WESTMORELAND, of Atlanta, Ga. These claim that the fever is indigenous, that it belongs exclusively to malarial countries, and cannot be introduced where malaria does not exist.

Secondly, there are those who reject malaria, as well as contagion, and maintain that the yellow fever arises from the effluvium of crowd poison and putrefactive changes, and that it is closely akin to typhus, and has nothing to do with malarial fevers. Thus, Dr. J. B. C. GAZZO ("Yellow Fever Facts," 1878) asserts he has seen it arise in ships from healthy ports, in persons who had been in no way exposed; yes, even in midwinter, in Montreal, Canada!

Thirdly, the majority incline to the belief that it is a specific and peculiar contagion, quite distinct from both typhus and malarial poison, though becoming more malignant in an atmosphere impregnated with either of these septic influences. This poison can be conveyed by fomites, and has certain peculiar, perceptible characteristics.

To this third view we strongly incline, as it seems the only one capable of explaining many facts connected with the epidemic.

It is stated that the disease first broke out in Memphis, this year, from the use of clothing which had been saturated with the poison of the epidemic of 1878. This would be denied by the malarialists. Thus, Dr. WESTMORELAND says ("Yellow Fever, its Origin," etc., page 13):—

"During the epidemic of last year a very malignant case, contracted in Memphis, arrived in Atlanta a few hours after the attack, bringing a package of clothing which was opened in presence of the nurses and physicians, all of whom, four in number, were in almost constant attendance in the room where the clothes were opened, and where the patient remained till his death. The result of this, as in similar instances, repeatedly before, proved the impossibility of communicating the disease by personal contact, or fomites from clothing."

Now, let it be remembered that such merely negative evidence is of very little weight; and then, if the statement in the last sentence is correct, how can the following true record be explained, which we quote from Dr. THOMAS F. ROCHESTER'S "Address on Epidemiology," at Atlanta, in May:—

"In September, 1856, an infected ship from Cuba was detained at the quarantine anchorage off Staten Island, New York. Several passengers had died, and some were ill on board. The garments and bedding were thrown overboard. Bay Ridge, a delightful suburban neighbor of Brooklyn, the seat of choice country residences, lies directly across the bay, distant about one mile from the anchorage mentioned. The wind and tide deposited a number of the garments that had been thrown away on the beach which terminated the lawn of Col. Charles Prince, an old and respected resident. In taking his usual morning walk he discovered the clothing and examined it with his cane, not otherwise handling it. He had no suspicion that it came from quarantine, and never saw it again.

In four days he was taken ill, and died in a week, from yellow fever. The man who nursed him, and who had previously had yellow fever, took away with him the suit of clothes the Colonel was wearing, contracted therefrom the disease, and died. The son and daughter, adults, the Colonel's only children, were also attacked; the son died, and this was the commencement of an epidemic which destroyed many lives in a limited area, but which was stopped by enforced isolation and by destruction of bedding and garments. The clothing which produced all this evil had been saturated with salt water, and had been tossed by the waves for more then twenty-four hours before it made its fatal landing."

A fact which has not been sufficiently studied is the *perceptible* character of the yellow fever poison. The *odor* which patients throw off in this disease is said to be as marked as in small-pox. Even the effluvium which is given off by infected fomites is distinctly noticeable, and has an immediate and powerful effect on the system. This remarkable fact was observed in this city in the last century, and we have found it vividly described by CHARLES BROCKDEN BROWN, who, a resident of Philadelphia at the time, describes the awful scenes during the yellow fever epidemic of 1793, in his powerful but little known novel, *Arthur Mervyn*, published in 1799. We quote from that work the graphic description that the hero gives of his entrance into an infected house in Fourth street. He had just come from the country, and had never before been exposed to the poison:—

"I mounted the stair. As I approached the door of which I was in search, a vapor, infectious and deadly, assailed my senses. It resembled nothing of which I had ever before been sensible. Many odors had been met with, even since my arrival in the city, less supportable than this. I seemed not so much to smell as to taste the element that now encompassed me. I felt as if I had inhaled a poisonous and subtle fluid, whose power instantly bereft my stomach of all vigor. Some fatal influence appeared to seize upon my vitals; and the work of corrosion and decomposition to be busily begun. * * * The pang with which I was at first seized, and the momentary inclination to vomit which it produced, presently subsided. My wholesome feelings, indeed, did not revisit me, but strength to proceed was restored to me."

How accurate and life-like this description is we never appreciated until we read a strikingly similar history in the St. Louis *Medical and Surgical Journal*, in some remarks on yellow fever, by Dr. REUBEN A. VANCE, of Ohio. Dr. VANCE, last summer, had in charge the infected steamer "John Porter," which disseminated the seeds of the disease near Gallipolis, Ohio. On the bed of one of the cases was a fine white spread, which had become somewhat stained with blood. Dr. VANCE continues:—

"When the bedding was destroyed, this spread was laid aside, removed to an adjacent house, and a woman of the neighborhood employed to wash it, some excuse being made for its condition. This woman, utterly without knowledge of the antecedents of the article she was engaged to cleanse, took a tea-kettle full of hot water and started to pour its contents over the spread, which had been thrown into a tub, but had neither been soaked in hot water nor disinfected. When the fumes arose and enveloped her, she suddenly stopped and sat down. Shortly after she made the remark that she was sick at her stomach; that her breakfast had disagreed with her. Within a week afterward this woman took the fever and died, and her name figures in the death-roll of those who had been on the Porter."

With such striking instances before us, we cannot but regret that any prominent physician should continue to defend the untenable and dangerous theories that the disease is either essentially malarious, of a typhus character, or indigenous to any part of this country.

NOTES AND COMMENTS.

Therapeutical Notes.

MODIFIED DOVER'S POWDER.

Dr. Tully's popular modification of Dover's powder is, according to Mr. Wood, of New Haven, prepared as follows:—

℞. Morphiæ sulphatis, 1 part
Pulveris camphoræ,
Cretæ precipitatæ,
Pulveris glycyrrhizæ, of each, 20 parts. M.

This is the original formula of Dr. Tully.

According to the same authority, the "Camphorated Dover's Powder" of Dr. Eli Ives is as follows:—

℞. Potassæ bitartratis, 8 parts
Pulveris camphoræ, 2 parts
Pulveris ipecacuanhæ,
Pulveris opii., of each, 1 part. M.

CARDIAC DYSPNŒA.

Prof. Sée, of Paris, advocates the use of iodide of potassium in cases of continuous cardiac dyspnœa, either alone or combined with opium, digitalis or chloral, beginning with doses of 1¼ gram, and rising gradually to 2 or 3 grams, to be continued for some time. Opium is added, in doses of from 10 to 15 centigrams, in order to

counteract the effects of iodine; and chloral is useful in cases where digitalis is not tolerated. The prescription would then be as follows:—

℞. Gum julep, 120 grams
Iodide of potassium, 2 "
Hydrate of chloral, 4 "

Sig.—To be taken in quantity as required, every two hours during the day.

ENURESIS IN CHILDREN.

Some recent British writers state that after numerous failures with all orthodox modes of treatment, it was found that cutting off meat in the diet was sufficient, in many cases, to effect a rapid and permanent cure.

BENZOATE OF SODA IN DIPHTHERIA.

Prof. Klebs, of Berlin, recommends this treatment. He prescribes—

℞. Sodii benzoatis, 5 grams
Aquæ destil.,
Aquæ menth. pip., āā 40 "
Syrupi cort. aurant., 10 " M.

Infants under one year are given a dessertspoonful every hour. Children from one to three years old must take a larger dose, viz., a tablespoonful every hour, the proportion of the benzoate of soda being also increased from 5 to 7 or 8 grams. To patients from three to seven years old, 8 to 10 grams are given; those over seven, from 10 to 15 grams. Adults should take from 15 to 25 grams in the same solution, the proportion of the solvents and the syrup remaining the same. The diphtheritic membranes were powdered with benzoate of soda, in severe cases once in three hours, in lighter cases from two to three times daily.

MUSK IN INFANTILE COLLAPSE.

In conditions of great debility and collapse in infants, Dr. A. Jacobi, of New York, recommends *musk* as the most efficient remedy known to him. Five to ten grains should be given at once, and repeated every half hour or hour. Two or three doses will be enough. It must be remembered that musk is frequently spurious or adulterated.

INFANTILE INTERTRIGO.

In fresh cases of this complaint, Dr. A. Wertheimer, of Berlin, praises Hebra's ung. diachylon, while for more severe cases he always uses corrosive sublimate, which he finds always successful in the shortest time. He applies on cloths a solution of one grain to four ounces of water, applying fresh cloths three or four times a day, and letting them remain on for about an hour each time, or even keeping them continuously applied. He has never seen any evil effects from absorption of the sublimate.

Subcutaneous Injection of Ergot in Neuralgia.

Dr. Marino, of Palermo, quoted in the London *Medical Record*, publishes the results of his experiments with ergot. 1. In tic douloureux local injections of ergot give better results than any other remedies, quinine included. 2. The results are equally as good in hemicrania. 3. In some cases of sciatica very good results have been obtained, while in other cases no relief has been afforded to the patient. 4. Ergot should be administered in other cases of neuralgia, especially if the latter is caused by blood poisoning or cachexia. 5. The injection itself is often painful, but abscesses do not often supervene. The pain generally ceases in half an hour, especially if a cold compress has been immediately applied to the place. 6. The neuralgic symptoms, as a rule, disappear after one or two injections; but it is advisable to continue them for some time. 7. The dose for one injection varies from 15 centigrams to 2 decigrams of ergot, dissolved in water or glycerine.

The Inhalation of Oxygen in Anæmia.

Everybody knows how difficult it is sometimes to get some much enfeebled chlorotic patients to take reparatory aliments, so great is their disgust for all azotized aliment, vomiting often ensuing when they attempt to eat meat. Some women live upon a little bread and salad, and the quantity of urea they eliminate is then very small, sometimes as little as from four to six grams in the twenty-four hours. In such women treatment becomes very difficult, it being nearly impossible to reproduce appetite in them. In these cases Dr. Hayem, of the St. Antoine Hospital, Paris, employs a means which has furnished most excellent results, and which consists in the daily inhalation of oxygen. The appetite soon returns, the vomiting disappearing at the same time; and so well do the patients then support azotized aliments, that the four regular "portions" of the hospital diet scale become insufficient.

Shock as Curative in Epilepsy.

It is not unknown that a sudden and violent shock will sometimes check an epileptic fit. An instance was reported some years ago in this journal (volume xx, page 145), by Dr. J. C. Pearson, in which a confirmed case was cured by an extensive accidental burn. Possibly the counter irritation also had something to do with it. The actual cautery and the seton are very valuable, and occasionally sufficient aids to the restoration of some patients.

Herpes Labialis in Pneumonia.

A correspondent in Paris writes that at a recent clinical lecture Prof. Sée made some remarks on the significance of herpes labialis in cases of pneumonia. This eruption, he stated, generally appears from the third to the fifth day of the pulmonary affection. It cannot be considered a critical eruption, as the lung symptoms continue, and the fever, on the contrary, is increased, the latter subsiding with the cure of the pneumonia, which takes place on the seventh or eighth day. In the latter case the urine, which during the course of the disease contained large quantities of urea, now becomes "jumenteuse" (resembling the urine of the mare); that is, it contains uric acid, indicating the decline of the disease. Even this latter phenomenon he does not consider a critical evacuation, as it is simply an effect of defervescence, or a favorable turn toward recovery. Prof. Sée does not believe in the humoristic doctrine, nor in the critical evacuation of the peccant humors of the body. According to him, the herpes labialis occurring in pneumonia has no other value than one of prognosis, as it is a favorable sign, from which a physician may with certainty prognosticate a favorable termination. But, as it happens that the fever increases after this, the friends of the patient, losing confidence, call in another doctor, generally a homœopath or other quack; and as the case generally gets well in two or three days afterward, the homœopath gets the eredit of the cure.

Mammary Inflammation Treated by Ice.

A writer in the *British Medical Journal* says that the suggestion of treating threatened inflammation of the mammary gland by ice was "one of the most valuable hints he ever got." He thus describes its use in a case:—

"I used a large Chapman's spine-bag, filled with ice, which encircled the lower half of the breast. It felt very cold indeed for a minute or two, then a considerable quantity of milk was shot out, as from a syringe (no milk had flowed before), the pain abated, and in an hour was almost gone; I now renewed the ice in the bag, and the patient kept it closely applied with her arm, which was protected from the cold by a folded towel. Next morning, I found her hugging the ice-bag and loud in its praise. She continued suckling her infant; but she suggested that the baby should not be put to the breast oftener than two or three times in the twenty-four hours. On the fourth day after the commencement of the ice the most careful examination failed to detect anything wrong in the breast, and she is now quite well and nursing her child. No other remedies were used."

Correspondence.

The Effects of Internal Parasites.

Ed. Med. and Surg. Reporter:—

I would hardly presume that there are many reading men in our profession who could derive much benefit from the pleasant criticism upon Dr. Shiver's article, "A Troublesome Parasite." I will not presume that there is a single physician who read Dr. Shiver's article at the time of its publication, who had ever practiced in a malarial or fruit growing country, but what, from Dr. Shiver's own statement of the case, diagnosed it immediately as a case of quotidian intermittent, with torpid liver. And if the Doctor had been so fortunate as to have given his alterative doses of calomel at the beginning, to have been followed with quinine, we would not have heard of his troublesome parasite. If, as Dr. Henning says (Reporter, July 26th), a "large number of such cases come under his treatment each year," he must be aware of the fact that worms in children seldom cause any trouble, except when there is a large accumulation, or the child becomes diseased otherwise. In fact, in some localities worms in children are very much like botts in horses. There are but few horses that have not botts. All farriers will tell you that a bott will not perforate or otherwise injure a horse unless the stomach becomes diseased from other causes, cutting off the supply of mucus from which the bott receives its sustenance, when it will begin to bore.

Dr. Rush says, "when we consider how universally worms are found in all young animals, and how frequently they exist in the human body without producing disease of any kind, it is natural to conclude that they serve some useful and necessary purpose in the animal economy."

Meigs and Pepper, speaking of the frequency of worms, say: "Their importance as a cause of disease has certainly been, and is still, by many physicians, and especially by the public, very greatly exaggerated."

It might be that all children that come under Dr. Henning's care are wormy; if such is the case, the Doctor would be justified in beginning all of his intermittent cases with some anthelmintic. But we, who only see worm cases occasionally, and the symptoms as described by Dr. Shiver's frequently, would prefer another line of treatment,

R. A. Dodge, M.D.

Collinsville, Texas.

[It is true that various recent authors maintain that the ill results to health consequent upon the presence of internal parasites have been greatly exaggerated. But there are indications at present of a reaction against this opinion; and we have noted a number of late papers setting forth strongly the probability that the old opinion was correct.—Ed. Reporter.]

Consanguineous Marriages.

ED. MED. AND SURG. REPORTER:—

I notice in the last issue of the REPORTER a short article on "Results of Consanguineous Marriages," taken from the Boston *Medical and Surgical Journal*. I think, from the statistics given there, that the conclusion arrived at is erroneous. Six per centum seems to me a very large proportion of insane people whose insanity can be traced to no cause other than consanguinity of parents, and thirteen per centum equally large for those cases traceable to all causes. It is altogether a different proportion to that of the race *in toto*, and ought to teach us a very plain lesson. Besides, in my experience with the fruits of consanguineous marriages, the large majority of the children, while they are not insane, and can frequently reason readily, lack that even balance of mental power which is wont to be termed common sense, and an uncommonly large proportion are, vulgarly speaking, half daft. I should never advise marriage between blood-kin, and think the danger from such union has not been exaggerated in the least.

M. H. C. WEAVER, M.D.

Ellsworth, Kansas.

Intestinal Worms and Intermittents.

ED. MED. AND SURG. REPORTER:—

In your issue of July 26, a communication from Dr. Henning, headed "Intestinal Worms as a Complication of Intermittents," suggests a report of a case under my charge in the County Hospital.

John Sammons, aged 8 years, reported as having chills every day about 3 P.M. I gave him ordinary treatment for several days, without any noticeable effect, the chills occurring as usual. I visited the patient, and although there were no very marked symptoms of worms, I gave him—

℞.	Santonin,	grs.ij	
	Sacch. alb.,	grs.xx	
	Calomel,	grs.iij.	M.

SIG.—Make powders 4 and give one every 4 hours, followed by a teaspoonful of castor oil.

The boy passed 39 large round worms within twenty-four hours after taking the first powder, and has never had another chill since, and that was the extent of the treatment.

A. A. ARMINGTON, M.D.

Greensburg, Ind., July 28, 1879.

NEWS AND MISCELLANY.

Report of the Autopsy of Mr. Charles A. Fechter, Tragedian.

At the request of Mrs. Charles Fechter a post-mortem was made upon the body of Charles A. Fechter, sixty-six hours after death, conducted by Prof. W. H. Pancoast, M.D., assisted by Dr. W. G. MacConnell and myself. The body had been well nourished. There was no *rigor mortis*. The abdomen was enormously distended with gas, and percussion showed that the diaphragm had been forced up, carrying the lungs and heart above the fourth rib. Engorgement of superficial veins over the sub-clavicular region, and also of the superficial epigastric veins, was displayed. The face was moderately jaundiced.

On opening the abdomen in the median line, the superficial fascia was one and one-quarter inches thick, and the omentum was loaded with adipose tissue. No gas was met with in the peritoneal cavity, but the stomach and intestines were distended with it. The stomach was normal in size; its mucous membrane thickened, pale in color and covered with a catarrhal discharge. The pylorus was thickened and slightly indurated, its mucous membrane presenting a similar appearance to the lining membrane of the stomach. The peritoneal covering of the small intestines exhibited some marks of inflammation, although no plastic material was detected. The peritoneal cavity contained about half a gallon of blood-stained serum.

Passing to the liver, it was found to be greatly enlarged, its right lobe extending far below the twelfth rib, with its left projecting into the left hypochondriac region; the gall bladder being correspondingly enlarged and partially filled with bile; the whole weighing 9½ pounds, or more than 5 pounds above the average healthy male liver. It presented externally a thickened, opaque and adherent capsule, under which could be seen and felt distinctly characteristic hemispherical granular bodies. The broad ligaments were thickened, and prolongations of fibrous bands were attached to the diaphragm and stomach. The gland was indurated and the edges rounded. Opening the organ, cirrhosis was found to exist throughout the entire structure, with its concomitant fibrous degeneration of blood vessels.

The microscopial examination, made by Dr. MacConnell, revealed lardaceous or amyloid degeneration. The *alumen* of the vessels were contracted, and the bright, shiny appearance of amyloid infiltration was well shown. The dépôts of amyloid matter were surrounded by large bands of connective tissue, not unlike the stroma of a carcinoma. Dense masses of connective tissue were seen; the cells at some points had undergone fatty degeneration. Examining the kidneys, the right weighed eight and a half ounces, the left being half an ounce lighter (normal weight of male kidney 4¼ to 6 ounces). Both were highly injected with blood, softened, long and flabby. The capsules were easily detached.

The spleen weighed 15 ounces (or more than 8 ounces above the average), occupied its normal position, and was exceedingly pulpy.

The heart, weighing 16 ounces, was found forced from its natural position, its apex lying opposite the superior border of the fourth rib. Thick deposits of adipose tissue covered the anterior external aspect of the pericardium. No fluid was found within the sac, nor was there any evidence of past inflammation of this membrane. The heart measured, from base to apex, 6 inches, and in circumference at the base, 11 inches. A blood clot was found in the left auricle, with slight thickening of the aortic semilunar valves. The other valves were normal. There was marked thickening, with fatty degeneration, of the ventricular walls. The inferior borders of

both lungs corresponded with a line drawn along the fourth intercostal space, and were congested and freely mottled with carbonaceous pigmentary deposits. There was nothing to indicate former pulmonary disease. The skull cap was removed and the brain exposed. Evidences of arachnitis, with effusion of serum into the arachnoid cavity, were at once apparent, and some lymph had been deposited on the upper surface of the membrane. The pia mater was injected with blood. The encephalon weighed 42 ounces, or about 7½ ounces less than the average male brain. Its texture was remarkably firm and well developed; the convolutions being fine, with deep *sulci*, the average measurement of which was 1⅛ inches. No signs of cerebral inflammation or softening could be found. The medulla oblongata and continuous part of spinal cord appeared sound and healthy.

When Prof. Pancoast and Dr. Shoemaker saw Mr. Fechter at his home, a few hours before his death, the most prominent symptoms were tympanitic distention of the abdomen, feeble action of the heart, hurried and difficult respiration, coupled with great prostration. His intellect was clear until within a few minutes of death. Stimulants were administered, and Dr. Pancoast attempted to unload the distended intestines by introducing the needle of a hypodermic syringe through the walls of the abdomen, but failed to give any appreciable relief, for the little instrument never penetrated the gut, so thick were the overlying structures. In reply to a telegram asking the nature of Mr. Fechter's disease, it was stated to be jaundice and paralysis, so that the probable use of an aspirator was not thought of.

In summing up the results of this interesting autopsy, and associating the morbid changes with symptoms known to have existed prior to death. the conclusion is that Mr. Fechter died from cirrhosis of the liver, and that the distended stomach and intestines was the immediate cause of dissolution, by interfering with respiration and the heart's action; if time and opportunity could have been given to aspirate the colon and relieve the distention, life might have been prolonged, at least for some hours.

CHARLES M. DRAKE, M.D.

American Dental Association.

This Association commenced its nineteenth session at Niagara Falls, August 6th. About one hundred members were present, and there were a number of able papers presented.

The Section on Education, through the Chairman, reported on that subject, and the following resolutions reported by that Section were adopted, after a lively discussion, occupying all the morning session:—

Resolved, That hereafter no dental college shall be entitled to representation in this Association that does not require a good English education as a preliminary qualification for its matriculants, to be ascertained by examination.

Resolved, That the colleges shall hereafter grant no diplomas, except to those who attend at least two full courses of lectures, excepting that practitioners of dentistry who present satisfactory evidence of having entered upon their practice prior to July 1st, 1875, and having continuously followed the same from that date, shall, until July 1st, 1885, be entitled to present themselves for examination for the dental degree, after attending one course of lectures in a duly recognized dental college.

Resolved, That no dental college shall be eligible to representation in this Association that does not, in its next annual announcement, give notice of its adoption of this limit to the conferring of degrees.

The Scapular Index in Man.

The scapular index is the expression of the relation of the breadth of the scapula to its length, and is found by multiplying the breadth of the bone by 100, and dividing by the length. After measuring several scapulæ, as we learn from the London *Record*, M. Broca has found that the average scapular index of Europeans is 65.9. He also measures the infra-spinous index, which is the relation of the breadth of the bone to the length of the blade below the spine. This, in Europeans, he found to be 87.8. He then compared these two indices with those of other races of men, and found that in the Australians, the negroes, and other low races, they are much higher.

Improper Imputations.

It is all very well for Dr. Henry A. Martin, inventor of Martin's bandages, to insist that those manufactured under his own eyes are the best; but when, as in the last number of the Chicago *Medical Journal and Examiner*, he accuses Mr. Ernest Hart, editor of the *British Medical Journal*, of deliberate falsehood and "cheating" his readers and brother practitioners about them, Dr. Martin commits an unbecoming act, and leads to the suspicion that questions affecting his own pocket are clouding his judgment and his sense of propriety. Mr. Hart is a thoroughly honorable man, and Dr. Martin will not help his cause by indulging in such improper imputations.

Sex and Color Colleges.

The law of this State used to exclude from voting "women, negroes, infants and idiots." But these classes are getting their rights, not only in voting, but in education. The women have medical colleges here and elsewhere, and Holloway, of pill notoriety, has commenced one near London, to cost $2,500,000, exclusively for that sex. While away down in Tennessee we note that the corner stone of a medical college building, which shall cost $10,000, was laid at Nashville, on May 15th, which is to be conducted in the interests of our fellow citizens of African descent exclusively, and will be ready to receive students in the fall.

Canada Medical Association.

This Association meets this year in London, Ontario, on the first Wednesday in September. It is expected that various representatives from this side of the line will be present.

The Quinine Trade.

The London *Chemist and Druggist*, July 15th, gleefully makes the following announcement at the head of its columns:—

"The abolition of the Customs duty on quinine was passed by the United States Legislature on July 1, and as a result the manufacture of the chemical in America is practically at an end. In anticipation of the inevitable American demand which this must occasion in Europe, a speculative movement has occurred here which has occasioned a general advance in the market prices of all kinds."

Personal.

—Dr. A. H. Appel, U. S. A., a well-known Pennsylvanian, has been assigned to the staff of General Miles.

—Dr. Edward Warren (Bey), the eminent American physician, has just received the decoration of Chevalier of the Legion of Honor. He resides permanently in Paris.

—Dr. Campany, the military physician who was engaged in the sanitary arrangements during the construction of the Suez Canal, is about to be sent to Panama to ascertain what measures will be necessary for the preservation of the health of the laborers who are to be recruited in South America for Mr. Lesseps' scheme.

—Dr. James L. Roberts, a highly respected citizen of Millville, Mo., while sitting in a store, on Aug. 4th, was accosted by Dr. J. L. Keyes, and charged with talking about his (Keyes') family. Roberts denied the charge, whereupon Keyes called him a liar, and drawing a revolver, shot him twice through the body, killing him. Keyes then mounted his horse and escaped.

Items.

—*Notice.*—We have a communication from Brooklyn, N. Y., without the name of the author attached. He will please write us.

—In the British House of Lords, recently, the Bill for the total abolition of vivisection was rejected by a majority of 81, only 16 voting for it.

—The mortality of Dublin was just about twice that of London in July; 36.4 against 17.4 per 1000 inhabitants.

—The *Chemiker Zeitung* says that a firm in Salamanca makes an incombustible paper by treatment with sulphate of ammonia, sulphate of magnesia, and borax.

—The Memphis Hospital Medical College is going to make another effort to begin this year. Its expected beginning last year was frustrated by the epidemic.

OBITUARY NOTICES.

—The *American Medical Biweekly*, Aug. 2, contains a sketch of the life of the late Dr. Wm. A. L. Potts, of Ashwood, La.

—The Chicago *Medical Journal and Examiner*, for August, contains a full notice of Dr. Theodore W. Stull, born in Smithport, Pa., 1833, died in Illinois, May 8th, 1879.

QUERIES AND REPLIES.

Reader X.—We have used the protochloride of iron as prepared by Rabuteau, although in but a few cases. It seemed to act quite well.

Dr. J. K., of Ill.—We can obtain for you any medical book in the market, and are willing to; but as we do not keep a stock on hand, please remit, with your order, the retail price, and we will mail you the book, postpaid.

Dr. Alphonso, Conn.—The plant you send is the common brake, *Pteris aquilina*. It has long been known to have astringent properties, but we question if it merits the praise you have heard given to it, as a remedy in diarrhœa, dysentery, etc. Perhaps some of our readers will throw further light on its medicinal properties.

Dr. L. S., of Mich., asks: Of two druggists in my village, I *know* one keeps the cheapest and poorest drugs he can get; the other much better. Have I a right to warn my patients against the former?

Ans.—Morally you have; legally, we suppose such a warning would be construed in law as a "privileged communication;" but we are not posted in the law of slander in Michigan, and you had better take counsel before saying much.

MARRIAGES.

CHAPIN—LEDUC.—On June 25th, by Rev. J. B. Donaldson, Dr. A. B. Chapin and Mary P. LeDuc, all of Hastings, Minn.

LAWRANCE—STUART.—In Pittsburg, on the 21st ultimo, by the Rev. Charles C. Thompson, D.D., Dr. E. S. Lawrance, of Philadelphia, and Miss Jeanie L. Stuart, only child of the late A. J. Stuart, of Pittsburg.

McCORD—HARRY.—On Wednesday, July 16th, at Sunny Side, Chester Co., Pa., by the Rev. Geo. G. Field, of Coatesville, Pa., Benjamin McCord, of Philadelphia, and Lydia, daughter of S. H. Harry, M.D.

WOODBRIDGE—MATHER.—In Williamstown, Mass., July 23, at First Congregational Church, by the Rev. Mark Hopkins, D.D., LL.D., assisted by the Rev. A. C. Sewell, L. Dana Woodbridge, M.D., and Abby Marvin, daughter of Benjamin F. Mather.

DEATHS.

AVERY.—On July 9, at Forestville, N. Y., Sherman S. Avery, of Petrolia, Penn., son of Dr. A. R. Avery, of Forestville, in the 29th year of his age.

BUCKINGHAM.—In this city, on the 25th ultimo, George B. Buckingham, youngest son of Dr. T. L. Buckingham, in the 20th year of his age.

CAMERON.—On Monday, July 7, Etta W., eldest daughter of Dr. J. G. and Mary Louise Cameron, in the 21st year of her age.

DE LA MATER.—At Duanesburg, N. Y., on the 9th ult., H. B. De La Mater, M.D., son of Stephen G. De La Mater, M.D., aged 28 years.

GOODALL.—In Bennington, Vt., July 10th, Finette, wife of F. W. Goodall, M.D., and daughter of Dr. J. F. Skinner, of Barton, Vt.

HEATH.—On Saturday, July 26th, 1878, in the 19th year of his age, Harry H. H., only son of Dr. A. Hawley and Mary M. Heath, of New York.

HYDE.—At Hastings-on-the-Hudson, Monday evening, July 28th, of cholera infantum, Edmund Cecil, youngest child of Dr. Frederick E. and Ida J. Hyde, aged 14 months.

LINDLEY.—In New York, on Wednesday, July 23d, Katharine C. Lindley, daughter of Dr. Willard Parker, and widow of the late Dr. Newton A. Lindley, aged 38 years.

SIMMONS.—In Westmoreland, Vt., July 2d, Dr. Barton Simmons, aged 78 years, 3 months.

DOCTOR RABUTEAU'S

(Laureate of the Institute of France.)

DRAGEES, ELIXIR & SYRUP

Of Proto-Chloride of Iron.

"The experiments made in the hospitals of Paris have demonstrated that *Dr. Rabuteau's Dragees, Elixir and Syrup* regenerate the red globules of the blood with a rapidity never observed with the use of the other ferruginous preparations. These results have been proved by the various *Compt-Globules.*

"The ferruginous preparations of *Dr. Rabuteau* do not cause any constipation, and are perfectly tolerated by the weakest persons."—*Gazette des Hospitaux.*

Dr. Rabuteau's Elixir is prescribed when some difficulty is experienced in swallowing the Dragees; it is especially adapted to weak persons, whose digestive functions need strengthening or stimulating.

Dr. Rabuteau's Syrup is especially prepared for children, who take it readily, because of its agreeable taste.

MEYNET'S

DRAGEES OF COD-LIVER EXTRACT.

Careful experiments have established the fact that the **EXTRACT OF COD LIVERS** contains very valuable properties, which render it superior to the ordinary cod-liver oil. It is composed principally of *Gaduine*, large proportions of *Iodides, Chlorides, Bromides, Phosphoric Acid, Lime, Soda* and *Ammonia*, and especially *Propylamin*, all of which enter, but in very small proportions, into cod-liver oil.

These dragees of pure cod-liver extract take the place of cod-liver oil, and have been used with eminent success by medical celebrities of Europe in cases of *Scrofula, Rheumatic Affections, Rachitism, Phthisis*, and in all cases where a propylamic medication is indicated.

MEYNET'S DRAGEES are sold in bottles containing 100 dragees. Dose, 2 to 6 a day. Each dragee is equivalent to two tablespoonfuls of cod-liver oil.

MEYNET'S GRAINS are small granules intended for children. 10 are equivalent to 1 dragee.

E. FOUGERA & CO., New York, Agents for the U. S.

RIGOLLOT'S MUSTARD PAPER.

Is one of the most important and useful discoveries of the age, but it is not (as certain dealers of bad faith pretend) a preparation that any one can make, for it is not manufactured with a mustard that every one can buy.

RIGOLLOT'S MUSTARD PAPER.

Is the invention of Mr. P. RIGOLLOT, who is the exclusive owner; it is the only preparation which has been adopted by the civil and military hospitals and the armies and navies of France and England, and which has obtained a medal at the Centennial Exposition at Philadelphia. All other mustard plasters, or leaves of whatever name, are but imitations of the original

RIGOLLOT'S MUSTARD PAPER.

Physicians will find it the most reliable sinapism, prompt and certain in its action, and will therefore always prescribe it. Every sheet in order to be genuine must bear the annexed signature of the inventor, *P. Rigollot*

Sold in tin boxes containing 10 sheets, also 25 and 100 sheets, by all respectable chemists throughout the world.

E. FOUCERA & CO., Agents,

NEW YORK.

PHOSPHOROLE.

PHOSPHORUS and COD-LIVER OIL

have now an established position throughout the civilized world as important therapeutical agents. A *perfect combination* of the two has long been a desideratum, since they are both of value in the same disorders, while the cases in which one is demanded and the other contra-indicated are exceedingly rare.

The combination in PHOSPHOROLE has the twofold advantage of furnishing *the best possible form* for the administration of *phosphorus*, and *a more effective form* for the administration of *cod-liver oil.*

With regard to the former, it has been decided by the highest chemical and medical authorities that *phosphorus* should be administered *in a free state*, and in a vehicle which ensures its *perfect diffusion*, its *absolute unalterability*, and, as far as possible, its *prompt assimilation* without the gastric irritation to which the ordinary methods of exhibiting the agent give rise. It is well known that pills, emulsions, solutions in ether, chloroform, vegetable oils and resin, etc., have all failed to fulfill one or more of these conditions. Even an ordinary solution of phosphorus in cod-liver oil would not answer the purpose in all respects. We claim, however, that PHOSPHOROLE completely satisfies all the conditions. From the method of preparing it, in an atmosphere of dry carbonic acid, the phosphorus is *entirely dissolved without oxidation*, and by our mode of manipulation *a positive uniformity of strength* is ensured. It is then promptly bottled and sealed, and its *stability and permanence* thus secured. The exact amount of phosphorus in each dose is known, its efficiency is ensured, and the irritant effects upon the stomach are reduced to a minimum by the blandness of the oil. As a means then of administering *phosphorus* in the many cases in which it is indicated as a *nervous tonic and stimulant*, it is claimed that PHOSPHOROLE is the best attainable in the present state of our knowledge.

The value of *cod-liver oil* in phthisis is so familiar to the physician that it is needless to dwell upon it. But the value of *phosphorus* is also universally recognized in this disease, especially when complicated with nervous derangements. The *combination* of the two therefore furnishes a more effective form for the administration of cod-liver oil in the great majority of cases in which that remedy is indicated, and one which will at once commend itself to the profession.

A dose of two teaspoonfuls of PHOSPHOROLE contains $\frac{1}{100}$ of a grain of phosphorus. This dose, when given after a meal, is effective, and not very liable to interfere with digestion. *Phosphorus is cumulative in its action, and should be administered with watchful care.* About $\frac{1}{12}$ grain is considered the largest safe dose, and we rarely need go higher than $\frac{1}{20}$ or $\frac{1}{30}$ of a grain. At the very first appearance of the smallest gastric derangement, the exhibition of phosphorus should be stopped.

PHOSPHOROLE is handsomely put up in pint bottles only, and may be obtained at all first-class druggists throughout the United States.

Descriptive Circulars furnished upon application.

LAWTON'S

ABSORBENT COTTON

FOR

HOSPITALS, DISPENSARIES, PHYSICIANS, DENTISTS, DRUGGISTS, PHOTOGRAPHERS, ETC., ETC.

The article furnished by us will be found superior to any other, on account of the facilities we possess for the manufacture, and the care taken at every step of the process.

Not only in general surgery, but especially in gynæcological practice, Absorbent Cotton has found great favor. It differs little from ordinary cotton in appearance, except in its uniformly fine quality and pure white color, freedom from all impurities — being entirely cleansed from oil, resin and all foreign matter.

The property of instantly absorbing liquids, its exquisite softness and great cheapness render it an invaluable substitute for Patent Lint, Charpie or Sponge.

We put up our Absorbent Cotton in neat and convenient packages, containing one pound, one-quarter pound, and two ounces.

A descriptive Circular will be forwarded on application. Samples containing two ounces will be sent, free of postage, on receipt of twenty cents.

PEPTONIC PILLS.

Pepsin, Pancreatin with Lacto-Phosphate of Lime and Lactic Acid.

(COPYRIGHT SECURED.)

This pill will give immediate relief in many forms of Dyspepsia and Indigestion, and will prove of permanent benefit in all cases of enfeebled digestion, produced from want of proper secretion of the Gastric Juice. By supplementing the action of the stomach, and rendering the food capable of assimilation, they enable the organ to recover its healthy tone, and thus permanent relief is afforded. One great advantage of the mode of preparation of these pills is the absence of sugar, which is present in all the ordinary Pepsin and Pancreatic compounds. In this form, the dose is much smaller, more pleasant to take, and is less apt to offend the already weak and irritable stomach. The results of their use have been so absolutely satisfactory, that we are confident further trial will secure for them the cordial approval of the Medical Profession and the favor of the general public.

Each pill contains one grain of pure PANCREATIN, which is equivalent to 10 grains of the ordinary or Saccharated usually prescribed and dispensed. Physicians will appreciate the great advantage of this mode of administration, the increased benefit to the dyspeptic being due to a full and effective dose of each, freed from unnecessary bulk, and really hurtful addition of sugar. A single pill will give immediate relief.

DIRECTIONS:—Take one pill immediately after eating or when suffering from Indigestion, Lump in the Throat or Flatulence. For children, reduce the pill to powder and give one-fourth or half, according to age.

DISEASES OF THE MIDDLE EAR—OTITIS MEDIA.

A paper read, by request, before the Delaware County Medical Society.

BY CHAS. S. TURNBULL, M.D.

REPORTED BY DR. W. MUIR ANGNEY.

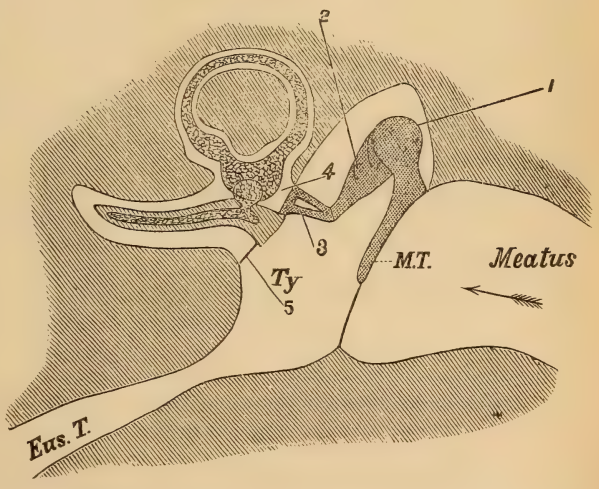
In studying diseases of the ear, our object should be to take as a basis the principles of pathology, and to reduce their treatment, local as well as general, to the recognized rules of modern therapeutics and scientific surgery; but above all should we labor to divest this branch of medicine of that shroud of quackery, medical as well as popular, in which, until lately, it has been enveloped.

To make the subject of aural disease acceptable and profitable to the student and general practitioner, it is requisite to simplify, as far as possible, the details of examination, and methods of treatment.

The ear admits of being correctly divided into two parts, viz., a *conducting* apparatus and a *fundamental* portion; but the usual anatomical division of it is into the external, middle, and internal ear.

Inflammation of this middle division of the auditory apparatus constitutes what is known in Aural Surgery as Otitis Media, and this term comprises not only inflammation of the cavity of the tympanum, but also the membrana tympani, the Eustachian tube and the mastoid cells, because, in a pathological point of view, the parts cannot fairly be separated. It is of the utmost importance for us, at the outset, to have a clear idea of the topographical anatomy of the tympanum, since most of the diseases of the ear occur in this space.

It will be best to consider somewhat in detail the several parts of the middle ear, in order to be able to trace the almost unlimited number of symptoms of an otitis media, and its effect upon contiguous organs.



M. T. Membrana tympani. *Ty.* Tympanum. *Eus. T.* Eustachian Tube. 1. Malleus. 2. Incus. 3. Stapes. 4. Fenestra ovalis. 5. Fenestra rotunda.

Instead of the demonstration made at the time of this lecture, from one of Prof. Azoux' large papier-maché models of the human ear, we have selected the accompanying sectional diagram,*

* Allen's Lectures on Aural Catarrh, London, 1874.

which will serve to illustrate the topography of the middle ear.

The tympanum represents an irregularly shaped octagon, its surface directed outward; or the *outer wall* may be described as the wall of the membrana tympani (so often incorrectly called the tympanum). The *inner* wall as the labyrinth wall; the *lower*, or floor, as the wall of the jugular vein; the *upper*, or roof, as the wall of the dura mater; while the *posterior* wall presents irregularly bordered openings into the appendix of the tympanum, the mastoid process; and *anteriorly* the tympanum terminates in the Eustachian tube, which serves for the escape of fluid as well as for ventilation.

Within the cavity of the tympanum are situated the ossicles, or ear bones (hammer, anvil and stirrup). These form an elastic vibratile chain connecting the outer with the inner ear, and serve to convey sound vibrations from the drumhead (membrana tympani) to the fluid in the labyrinth at the oval window (fenestra ovalis), which fluid will finally excite the fibres of the anditory nerve therein expanded.

In order to enable the membranes at either end of this chain of little bones to be tightened or relaxed, its mechanism is controlled by two muscles, the tensor tympani and the stapedius, which act antagonistically, although at times they seem to act together. Opposite the oval window, into which fits the foot plate of the stirrup, and on the other side of the promontory or prominence of the cochlea, is the round window (fenestra rotunda) or analogue, if we may use the term, of the Eustachian tube. Pressure inward, toward the vestibule and upon the fluid of the labyrinth, by the base of the stapes, is transmitted to the only movable portion, the membrane of the round window, and this, it is manifest, must bulge outward.

The Eustachian tube forms the communication between the tympanum and pharnyx, and serves at once for the escape of the tympanic secretion and as a passage for the renewal of air in the middle ear, so that the air therein contained shall always remain of the same tension as the outer atmosphere. By the act of swallowing the membranous wall of the tube is retracted, through the action of the tensor and levator palati muscles, and at the same time the tube is opened. The mechanical action of these muscles protects the orifice of the tube against the entrance of liquids and morsels of food; although sometimes, as in the act of sneezing and vomiting, as well as in cases of cleft palate, substances get into the tube.

The *mastoid cells* represent the air-containing cellular spaces; a kind of reservoir or pneumatic appendage, as Hinton called it, of the tympanum.

The muco-periosteal lining membrane of the middle ear throughout, is spread over every surface reflected around the little bones, their joints and the tendons of the muscles, and covers the internal surface of the membrana tympani, and the membrane of the round window. It extends into the mastoid cells, and is continuous, through the Eustachian tube, with the great gastro-pulmonary mucous membrane; thus possessing an intimate and extensive connection with the digestive and respiratory organs. It is in this manner that morbid impressions are conveyed, through sympathy or continuity, and become a cause of deafness.

The vessels of the middle ear are derived partly from the region of the external carotid (the stylo-mastoid and ascending pharyngeal); partly from the internal maxillary (the middle meningeal); and the internal carotid also gives off, during its passage through the petrous bone, some branches to the tympanum and Eustachian tube.

The nerves of the middle ear are derived from quite as many sources. Sensation is supplied to the mucous membrane by the glosso-pharyngeal and by the sympathetic. The otic or Arnold's ganglion—the special ganglion for the organ of hearing—is formed by branches from the fifth, from the glosso-pharyngeal and from the sympathetic. The tensor tympani and tensor palati muscles are supplied by the trigeminus, and motor internal pterygoid nerves of the third division; both receive, as well, a small branch from the otic ganglion. The levator-palati muscle receives its nerves from the vagus, and the stapedius muscle from the facial. Lastly, the chorda-tympani nerve, from the facial, passes through the tympanum without giving off any branches there.

Finally, the physiological function of the tympanum is to furnish a free space for the vibrations of the membrana tympani and the ossicles, and for the distention of the membrane of the round window, by which means vibrations of sound are collected, intensified, or, on the other hand, diminished, and delicately transmitted to the fluid of the labyrinth and auditory nerve. Any change within this space which can produce any obstruction to the free vibration of these parts must be the cause of disturbances of hearing.

In considering the morbid changes that occur in the auditory apparatus when affected by

catarrh, or by the exanthematous disorders (especially scarlet fever and measles), we will find that the middle ear, or tympanum, is the part of the organ implicated.

This manner of dividing the subject will eliminate from our present design very many of the diseases of the external ear—the auricle and meatus—as well as those of the internal ear, consisting of the nervous portion and labyrinth. Even though we exclude all those disorders not arising from, or complicated with, any abnormal condition of the middle ear, its contents and appendages, it may still be safely asserted that in fully five-sixths of the cases which come under the notice of aural surgeons the disease and accompanying deafness have originated in the mucous membrane lining the throat, nasal passages, Eustachian tube and cavity of the tympanum.

Diseases of the middle ear or tympanum are best divided into the three following forms:—

(*a.*) Catarrhal inflammation (otitis media catarrhalis).

(*b.*) Purulent inflammation (otitis media purulenta).

(*c.*) Plastic or hypertrophic inflammation (otitis media hypertrophica).

All varieties of inflammation of the middle ear resolve themselves into one or the other of these forms, and becoming chronic, or terminating as an acute or subacute attack, can be traced out, and as the disease progresses our diagnosis can be more precisely made.

(*a.*) Catarrhal inflammation (otitis media catarrhalis), or simple aural catarrh. This form may be divided into *acute* and *chronic.*

Acute inflammation of the lining membrane of the tympanum is one of the most painful affections from which poor humanity must suffer. It may occur at all periods of life, but is generally a disease of youth, and seldom seen beyond middle age. It is usually induced by some definite cause, as cold, occurring, for instance, after "catching cold," getting the body, or more particularly the feet, wet; sudden exposure to a low temperature, blasts of harsh, cold wind, surf bathing, diving in cold water, sneezing, vomiting, riding in draughts in carriage or railway cars, and is generally seen in connection with catarrhal inflammation of the naso-pharyngeal passages, or less frequently, with bronchial catarrh. The lower or facial portion of the Eustachian tube is involved in nearly every severe case of coryza or acute naso-pharyngeal catarrh; and in the cases of persons particularly predisposed there is always induced what may be called tubal catarrh. In some there seems be a peculiar tendency to inflammation of the naso-pharyngeal mucous membranes, and in such we must frequently find this variety of ear disease.

Loss of hearing generally occurs suddenly, and the impairment is usually of a high degree, although, on the other hand, an accession of pain at the middle or toward the end of the night is the first warning the patient receives. In many of those violent cases of screaming (occasionally convulsions) with which children are awakened out of sleep, an acute catarrhal otitis media is the cause. The pain is described as of the most excruciating character, and is usually compared to a "knife being thrust into the head." It may only be felt at intervals, but it is sure to be exacerbating at night, and it is more on account of the loss of sleep that the patient is so quickly prostrated. At times the patient escapes with nothing more than a sense of fullness or pressure in the ear, but in most cases the pain is of a deep-seated character and is dull and aching, and of an incessant, throbbing nature. Traction upon the auricle does not always cause pain, but pressure in front of the ear—upon the tragus—is more than painful, while the act of swallowing, motions of the jaw, coughing, blowing the nose, straining, and especially sneezing, are simply torture. Drinking cold fluids is also a cause of pain, as well as provocative at such times of neuralgic toothache. Tinnitus of many varieties (buzzing, hammering, booming, etc.) add to the patient's misery, and these noises in the ear are so disturbing that patients are often at a loss to know whether they are not actual ones, made near them. Giddiness may, at times, be present, and in those cases in which the fever is very severe, and the pain is more diffused over the head and less confined to the ear, while the difficulty in hearing is scarcely noticeable, the origin of the disease may easily be mistaken for congestion of the brain or meningeal irritation. Vertigo may be felt even while patients lie quietly in bed; the febrile symptoms may increase in the evening, almost to delirium, and it is no difficult matter to picture the anxious, staring countenance of a patient reduced and excited by loss of sleep, fever, and pain; to say nothing of the accompanying deafness and demoralizing tinnitus.

Therefore is it especially difficult, in the case of children, to distinguish between acute aural and cerebral disease.

Facial paralysis, from involvement of the portio dura, through swelling in its neighborhood, is sometimes seen, and should this attack be due

to exposure to cold, there will be more or less of a mucous discharge from the nose, with stuffing of the frontal sinus, acute frontal pain, redness of the conjunctiva, photophobia and lachrymation.

As regards the objective symptoms, it is true we do not require more than we have described in a general way, but for the importance of a more minute diagnosis we must inspect the meatus or auditory canal, which may or may not be swollen, even to occlusion. Should the canal be unobstructed, we will find the membrana tympani of a dull white or brownish color; all its opalescent lustre will have disappeared; the handle of the malleus will be pink, scarlet or brown, or, when the membrane bulges, it is not discernible at all. Later, that is after several days, the mastoid process may be swollen, red and painful on pressure, and simple motion of the head may be impossible. Politzer describes the membrana tympani, in such cases, as generally looking like a polished copper plate.

In addition to these local symptoms, there is more or less fever, the tongue is white, dry, and even furred; pulse quick, skin dry, bowels constipated, urine scanty and highly colored, but *intense thirst is rare.* The countenance indicates agony, and the patient cares but little for external surroundings, and tosses the head from side to side and moans. Partial coma we have seen but seldom present.

The prognosis is so far favorable. The immediate termination of the disease is threefold, *i. e.*, *resolution*, *perforation* and *extension* to vital structures.

In *resolution* the pain gradually subsides, and if there be swelling, as is rarely the case in this catarrhal form, this also disappears, and hearing is restored, although a certain amount of fullness and tinnitus (of a buzzing or ringing nature) remains for a considerable time.

In this form the inflammation never goes on to the formation of pus. If serum, or even muco-pus, be poured out from the tympanic mucous membrane, it is absorbed, or has found a gradual exit through the Eustachian tube, leaving the membrane thickened, or its function more or less impaired.

Perforation of the membrane rarely occurs, and if at all, generally during violent sneezing or blowing of the nose, or it may be, unprovoked, accompanied by a loud report. Such perforations permit the escape of a small amount of serous fluid, after which the edges of the opening quickly unite, and in twenty-four hours no sign of rupture can be seen. Perforations are induced by the entrance of substances from poultices, or by fluids dropped into the meatus, as the parts thus encroached upon become irritated and macerated, and hence weakened.

The escape of the pent-up matter is always followed by an immediate sense of relief, thus showing that pressure by the fluid upon the unyielding structures of the cavity of the tympanum has caused the pain. The main point is, therefore, to evacuate the cavity of the tympanum of its contents, be they what they may, serum or muco-pus. This is best done, in the severer cases, by paracentesis of the membrana tympani (only when it bulges), and the blowing of the foreign matter through the opening by the air douche (Politzer's method here described) or by the catheter.

Seldom have we found it necessary to perforate in cases of simple aural catarrh, as a good blast from the air douche usually disseminates all the intra-tympanal fluid, especially when the patient can be instructed in the application of Valsalva's method of inflation of the tympanum (self-inflation of air, with closed mouth and nostrils, after a previous deep inspiration).

By *extension*, we mean a continuation of the previously enumerated symptoms. The intra-tympanic secretion, from mucus and muco-pus changes to be a true pus (often ichorous), the mastoid cells become clogged, through an extension of the inflammatory process, the Eustachian tube is closed, the membrana tympani becomes thickened, and burrowing commences. The periosteum (mucous membrane of tympanum) is lifted up, and the inflammation is propagated to the dura mater through the thin lamina of bone, or it spreads, by way of the round or oval windows, into the labyrinth, and through the internal auditory meatus into the brain, causing meningitis or cerebritis, or even abscesses, by pressure, may form in the substance of the brain. The latter course, in cases of acute aural catarrh, is rare, but, nevertheless, cases are on record where the process described ran its course within a short time and terminated the life of the patient. Pain in acute inflammation of the tympanum is at times the cause of delirium, which symptom often misleads the novice.

Treatment of acute inflammation of the middle ear is most satisfactory, and by it most of the well earned laurels which crown the monotonous labor of the otologist are to be won. Local blood letting is first called for in every case, either by leeches, the artificial leech, or wet cups, or even scarification of the tragus and post auricular tissues. The American leech must be freely

used, while of the Spanish, the best, from five to eight are generally sufficient. The effect may be increased by encouraging the bleeding by hot fomentations, to the bites. The effect of local blood letting in acute aural disease, in relieving the intense pain, is magical, and with morphia used internally we are sure of affording prompt relief.

Where fluid of considerable quantity can be diagnosed within the tympanum, the membrana tympani may be perforated, and where the fluid is not satisfactorily diagnosed, the air douche can, with safety, and generally with success, be used. Heat and moisture, from poultices or fomentations, are next called for (the substance of the poultice in no case to come into contact with the ear, lest it enter and clog the meatus. The next best application, instead of a poultice, is a cloth wrung out of hot water, or better, spongio-pyaline, and covered with oil silk. A cathartic, composed of from two to three grains of calomel and five to eight grains of jalap, should be given. As an anodyne, morphia has been pronounced of unusual efficacy, and we would testify in its favor; it seems to be especially indicated in these cases, and is, with few exceptions, well borne. It can be given by the mouth or hypodermically, gr. $\frac{1}{8}$, at a dose, every half hour until relief is obtained. The old-fashioned remedy, of a bag filled with salt, chamomile flowers, or hops, must not be ignored, as, like most home-made remedies, it is good. In lieu of anything better hot water can be poured into the meatus with a teaspoon, at intervals of an hour, and allowed to remain fifteen minutes. This latter method is a good one in camp, or in places where hospital conveniences are not to be had. The severe pain will usually cease with this treatment, but the patient should remain in bed, while slight diaphoresis is induced by liq. ammon. acetatis or pulv. ipecac. comp.

The naso-pharyngeal catarrh should be carefully seen to, and as soon as the acute inflammatory symptoms have subsided, gargles of warm salt water, bicarbonate of soda and water, or alum or tannin in water, should be employed. Sage tea and alum, ℥j of the latter to Oij of the former, we have found very useful.

(*b.*) *Purulent inflammation*, in so far as it concerns the tympanum proper (time limits our going further), usually leads to rupture, ulceration and loss of substance in the membrana tympani, and continuous discharge of pus externally. This form of inflammation is often met with in nursing children, where a discharge existing for a month or more has, after careful treatment, gotten well, and no impairment of the function of hearing has followed, as we can testify after having watched such cases. The acute variety is common in following the acute exanthemata, typhus, tuberculosis of the lungs and syphilis.

The exudation may be pure pus, of a yellowish or yellowish-green color and creamy consistency, which causes the meatus to be filled; the pus may run into the concha, or even drop upon the shoulder. When the meatus is cleansed by syringing with warm water (which must be done before we can make a diagnosis), the shining, deep-red lining membrane of the tympanum, its surface denuded of epithelium, can be seen.

Just here we would pause and make the remark that many of the cases of chronic purulent inflammation of the tympanum are caused either by neglect or through dire ignorance. On one hand, persons will patiently permit the sense of hearing greatly to be impaired, nay, even lost, on one side, without making an effort for its restitution, and when the lapse of months, or even years, has contributed to confirm disease and render such persons incurable, they generally respond to inquiries with regard to previous treatment, that they did not like to be "tampering" with their ears, or that they had been told that nothing could be done for them. On the other hand, not only will ignorant, uneducated persons say "the discharge must not be stopped," "Oh! no, it will go to the brain," or "it is good to have running ears," but also those who are educated and who ought to know better will make similar stupid remarks, and entertain equally absurd opinions; and what is worse than all, they will assure us that "their family physician advised them to let the ear alone." This is not vain talk, but solemn truth, and any otologist will bear us out in this statement. Little to be wondered at is it, then, that acute inflammatory processes within the ear run on to destructive ulceration and a fatal termination.

In *chronic* cases of purulent inflammation the disease leads to hyperplastic processes in the mucous membrane, and where there is secondary ulceration (which is relatively rare) there may be a deep loss of substance in this mucous membrane, and caries of the ossicula and walls of the tympanum may occur; we have had small portions of the exfoliated bone and necrosed ossicula brought to us by observant patients. If the pus is stagnant for any long time, dried pus, fattty detritus, and cholesterine may be found, with epithelium cells, forming masses, which by drying and shrinking fill and irritate the cavity of the tympanum or mastoid cells. Granulations may spring from all

parts of the mucous membrane, and sprouting, fill up the tympanum and project into the external meatus, and within a few days cause increased or even total deafness of that side.

After the healing of a chronic suppuration of the tympanum, where a perforation of the membrana tympani remains open, it will frequently be seen that the epidermis of the meatus extends into the tympanum, and even into the mastoid cells, and this affords the surest protection against a recurrence of suppuration, and is especially desirable.

Polypoid masses (*i.e.* granulations) are to be cut away with the wire snare, and the parts touched with nitrate of silver, or better, carbolic acid; great care being exercised that no more acid than is actually necessary be used. The several conditions must be treated as they arise. In the case of sclerosis, where there is considerable hearing remaining, the ear should not be meddled with. Where there is no cerumen a substitute must be used.* Where both ears are without the membrana tympani, an artificial drumhead may be inserted; but the pledget of cotton soaked in equal parts of glycerine and water has been found of most service.

The most successful treatment is that which combines careful attention to hygienic and dietetic rules. Proper cleansing is in many cases quite sufficient for a cure. For this purpose a syringe, holding from four to six ounces, or a douche, may be used. Castile soap solution, the favorite ear wash of the laity, we would here condemn. Warm, always warm, solutions of salt or soda and water are the best, and should be used in the morning, never at night. They should be used at least one hour before going out of doors, and cotton placed in the meatus, to be worn there only when out of the house. The cotton should never, on any account, be worn in the ears at night. The discharge must have free exit. If allowed to back up upon the mucous membrane, it will ferment and prevent any possible healing process. We have found the absorbent cotton to be the best, as it soaks up the discharge and the wearer can renew the pledgets from time to time. Ordinary cotton only pens up the discharge. To the alkaline washes may be added carbolic acid or alum; we have used both with benefit. Of late, we have used with marked success powdered tannin and iodoform, one part of the latter to four of the former, dusted into the recently cleansed meatus. Caustic applications or solutions are in no case to be allowed in the hands of the patient. Such local applications are made through a large-sized vulcanite speculum, and by the light of a forehead mirror.

Where solutions are used, the head should be laid on a table with the diseased ear upward, and the operator should drop the warm solution in with one hand while he holds a moist sponge in the other, ready to catch any superfluous fluid that might accidentally run out of the ear, so as to save the patient's clothes and his own feelings, for nothing looks worse than a nitrate of silver-stained neck or cheek.

Be sure and allow the healing process a chance. Treat the symptoms. Keep the ear (tympanum) inflated by means of the air douche, and cleanse by syringing only when necessary. Perforations, even large ones, do heal, and the function of the membrana tympani will be almost restored. Pseudo-membrane only, but never the three-ply (mucous, fibroid and dermoid) membrane, is formed to close a large perforation or one of long standing.

Teach the patients how to care for their ears. Show them how to syringe or cleanse the tympanum, and how to dry the parts thoroughly, and also how to inflate the ear by Valsalva's method.

Syphilitic forms of otitis media, when taken in time, are quite amenable to treatment, and the method already described, with appropriate constitutional remedies, seldom fails. They are mostly of pharyngo-tubal origin.

Tuberculous otitis media we never saw cured, nor do we ever expect to cure such a case. Caseous inflammation, with the formation of miliary tubercle, in chronic purulent otitis media, is seen frequently accompanying pulmonary tuberculosis. In persons past middle life, too, we have yet to see a case of cure of chronic purulent otitis media, even in otherwise healthy subjects.

Counter irritation, by tincture of iodine, behind the ears and over the mastoid bone, acts as well, and is much less severe, than blisters, and we have found the combined effect of one coat each night to be much preferred.

Croupous, diphtheritic, or even gonorrheal inflammations of the middle ear, induced through inoculation by the towel or fingers, is seldom seen, but should be treated according to general principles.

Should an inflammation of the middle ear be allowed to run on through its chronic course,

* One grain of morphia and one grain of the yellow oxide of mercury to a drachm of cosmoline forms the best substitute for cerumen. It is to be used nightly or less frequently, as the more or less dry condition of the meatus indicates.

and perchance cease and heal, the connecting bands thrown out by contact of inflamed surfaces or by pathological action bind the parts together, or by sclerosis the parts are so contracted that the ossicles are crippled, their joints are anchylosed, and the result is most disastrous to hearing.

Before closing we must refer to "tinnitus aurium," or noises in the ear. This symptom occurring in the course of an acute inflammation of the tympanum is due to pressure by swelling, exudation and increased circulation. This latter form is, of course, the most amenable to treatment, and is the last lingering symptom in acute cases. In chronic suppurative inflammation the tinnitus often remains, and is caused by the constant rush of atmospheric air through a perforation in the membrana tympani, by a patulous Eustachian tube, or by the pressure of the swollen, sclerosed,—cicatricial—parts upon the labyrinthine fluid, through the stapes or thickened, unmovable membrane of the round window.

One form of tinnitus, known as pulsating, is caused by functional disease of the heart or arteries; it is more rare, and is quite incurable, as may easily be imagined, although there are rare cases of cure from ligation of the carotid. One well marked peculiarity to be noticed in all patients suffering from this form of tinnitus is, that they often suppose the noises they hear must be heard by others standing near, and it is sometimes well for us to give ear to their story, where we might often be inclined to smile. Patients' seemingly ridiculous suggestions are not always so absurd as they appear, and he who would learn will, at least now and then, stop and listen.

In conclusion, allow us to offer a protest against the promiscuous dropping of any fluid, even water, into the external auditory meatus, in cases of inflammation of the middle ear. Laudanum is considered as a panacea in all cases of earache, no matter from what cause it may have arisen; and drops, oils, and liniments, some of them of the most caustic nature, are, without mercy and without discrimination, poured into the external meatus, by those who, like the regicide of old—

> "Stole,
> With juice of cursed hebenon in a vial,
> And in the porches of the ear did pour
> The leprous distillment."

The late Sir William Wilde humorously but truly writes, and we quote his experience. "Friends often ask us, 'Have you found any new cure for deafness?' We do not propose to invent or introduce new remedies. We labor to make the well established rules of practice in the treatment of other organs applicable to the management of aural diseases. Like most students of our day, we were taught theoretically to believe, and practically to observe, that we 'knew nothing' about diseases of the organs of hearing." This was the dictum honestly expressed by the "heads of the profession," men from whom the public were willing to receive a fearless, candid opinion, either immediately upon being consulted or after a few trials of the "ordinary means," to wit, syringing with hot water and soap, either castile, soft yellow, or old brown windsor, *in the hope* that the deafness or the noise in the ears might arise from a collection of hardened wax; then settling the digestive organs by purgatives and a "course of bitters," lest the affection might be "owing to the stomach." The human stomach has much to answer for in deranging the system, no doubt; but the mischief of which it is daily accused, as every one extensively engaged in practice is aware, is beyond belief. There is scarcely a disease of the ear which we treat, no matter how local, upon which, if we question the patient as to its duration, he will not say, "Oh! it is, indeed, of pretty long standing, but I was waiting to have my stomach put to rights, as I am told that I am very bilious." Next in order, in routine practice, is blistering behind the ears, tried in order to draw away some peccant humor that had, *perhaps*, accumulated around the delicate organ of hearing.

These, and like methods, failing to give relief, stimulants, often of a very acrid nature, are poured into the external auditory passages, either to restore the secretion, under the impression that what is a mere attending symptom is the disease, or to excite or arouse the dormant nervous power; and hot tinctures, turpentine, creasote and pungent essential oils, are applied to the external surface of the tympanal membrane without mercy. Some physicians resort to more palliative means, recommending some warm almond oil to be dropped into the ear at bedtime, or eau de cologne to be rubbed upon the side of the cheek adjoining the auricle, at the same time advising a little black wool to be retained in the meatus in order to preserve the organ from exposure to cold. To give, however, fair play to the latter remedy, it should be prescribed in full; and according to the old popular superstition, which is still extensively adhered to, the wool should be procured from the left forefoot of a six-year old black ram! Some advise a slice of fat bacon to be inserted into the meatus every second night; and now glycerine has become the fash-

ionable remedy. All these various means having failed to give relief, the patient is recommended —an easy mode of getting rid of him—to give galvanism and electricity a fair trial; and if they do not succeed, change of air and scene, sea bathing, or a "course of waters" at some of the fashionable places of resort is prescribed. Despairing of relief from the legalized practitioner, and becoming disheartened at the different opinions from men of repute and eminence, we need not wonder that suffering patients throw themselves into the hands of quacks and nostrum mongers.

INUNCTION IN SCARLET FEVER—IS IT A PROPHYLACTIC?

Read before the Northern Medical Association of Philadelphia,

BY JAMES B. WALKER, M.D., PH.D.,

Professor of Practice of Medicine in the Woman's Medical College of Pa.

In the absence of our regular essayist for this evening, I will, with your permission, introduce some thoughts for your consideration, concerning the use of inunctions in scarlet fever; and more particularly to the fact that in addition to their usually ascribed benefits I believe them to deserve the additional one of being *prophylactic*.

As conservators of the public health, and especially of the health of those families entrusted to our care, the matter of prophylaxis is of the utmost importance to us. Scarlet fever is believed to arise by contagion in the vast majority, if not in all, cases, being transmissible from the sick to the well, either by direct exposure or indirectly by fomites.

The agents which have enjoyed a reputation as prophylactics in this disease are of such a character that the healthy must take them in order to serve as antidotes to such poison as may be absorbed. Belladonna for a time enjoyed quite a reputation in this respect, and is still employed quite extensively by many practitioners; where, however, it has been subjected to careful experiment, it has repeatedly and utterly failed as a protective, and hence our faith in it has been lost. Numerous agents have been recommended for their supposed power to disinfect the tissues of those who are exposed to the poison, so that the would-be destroyer is destroyed. Among the latter is sulpho-carbolate of sodium, recommended by Drs. Brackenridge and W. Scott, and reputed to have proven satisfactory in doses of from 5 to 30 grains, according to the age, and to be repeated three or four times daily. However successful these agents may prove themselves to be, they will seldom be thoroughly and extensively employed, because they necessitate the dosing of the *well*, and that not always with the most palatable substances.

In treating some cases of this affection recently, my attention was directed to the results of inunction; and I am forced to believe that in this method of treatment we have a prophylactic agent which possesses some advantages over many of those previously mentioned. The chief advantage it possesses is that the *infected organism receives the treatment*, and not the healthy ones; and further, that the treatment is directly beneficial to the patient also.

Inunctions, though recommended by most authorities on scarlet fever, are too frequently either slighted entirely, or else very unsystematically employed by many practitioners. The rubbing with fat bacon, advised by some neighborly old lady, is acquiesced in because it will do no harm, and may make the attendants feel that they are doing something in the way of help. Others direct that inunctions be used, without detailing the method of application or frequency.

The importance of the treatment will be readily understood by a little reflection. The chief symptoms of the early stage of scarlet fever are intense itching and consequent restlessness, which latter may gradually shade into convulsions. By allaying the itching the restlessness may be almost or entirely prevented, as abundant evidence testifies. The child tossing and crying in its wretchedness is soothed into a quiet slumber as the well-oiled palm traverses its surface, and the convulsion which seemed imminent is warded off. So much for the oiling as it is generally employed.

In the first of the cases which fell into my hands during the past winter I used the inunction every two hours, or more frequently if the child became restless. Instead of ceasing the inunction as the febrile and restless stage declined, I decided to continue it, with the idea of avoiding the dangers of exposure after the hot bath (95–98° Fahr.), which the child was receiving night and morning. Anointing with warm sweet oil was directed after removal from the bath, the same to be repeated at intervals of four hours between baths. Although the child had a profuse eruption, the desquamative stage could scarcely be called such, there being no free scaling whatever. The skin was pliant, soft and secretive, markedly in contrast with the usual dry, rough skin of this stage, even where desquamation is not excessive. I concluded that

something was gained in keeping the skin in this secretive condition, by avoiding, in a measure, at least, the dangers of nephritic trouble, so frequent and so serious as a sequel to this disease.

I was still more impressed with the entire absence of free scaling. On inquiry I learned that scales were quite perceptible in the water of the bath. The inunctions had succeeded in keeping those which were proliferated in contact with the skin, until removed therefrom by the bath. The query, therefore, presented itself: If, as is generally conceded, the epidermic scales are loaded with the scarlet fever poison, and furnish the chief means of spreading the disease, *will not any means which prevents their free escape be so far a measure of prophylaxis?* Acting upon this suggestion, I have treated the cases which have since fallen under my care accordingly; and although some of the cases had the eruption in an intense degree, yet in no case was there more than the slightest desquamation, and in none were the few scales formed found lying freely and loosely upon the surface, nor entangled in the gathers of the garments. In no case was there an instance of contagion. However, the number of cases have been too few to draw any just conclusion as regards the success of the measure as a prophylactic.

The advantages of inunction are patent in every stage of this disease; and, while other remedial agents may be called for by special symptoms varying with the case, no case, however slight, can be other than benefited by judicious and systematic inunction. Its claims for more general use rest upon the following facts:—

1. Its action during the febrile stage removes restlessness, lessens the liability to convulsions, and insures healthful sleep.

2. Continued in the post-febrile stage, it keeps the skin in a secretive condition, thus rendering dropsies, etc., due to nephritic implication, much less liable to occur.

3. By lessening cutaneous irritability in the early stages, it directly lessens the amount of desquamation, thus immediately and measurably detracting from the number of agents engaged in the spread and continuance of the peculiar poison.

4. As seclusion of patients affected with this disease has proven to be at once the simplest and most efficient means of protecting the household, inunction perfects this seclusion, by entangling and retaining such scales as are proliferated until they can be removed by the bath, which, if thought necessary, may be medicated by a disinfectant. The ointment used for inunction may also be similarly medicated in cases of peculiar severity, or where desquamation is excessive.

5. This latter effect justifies us in classing inunction with the prophylactics of this disease; and until proven otherwise, I cannot but esteem it at once the most efficient of all the prophylactics, because of its universal application.

Medical Societies.

NORTHERN MEDICAL ASSOCIATION OF PHILADELPHIA.

At the meeting of the Society held in May, 1879, Dr. James B. Walker read a paper on

Inunction in Scarlatina,

which is given on page 162.

After its reading, the discussion was opened.

Dr. Rihl said he had been aware of the benefits of inunction in the early stage of this disease, and had employed it for several years; always with relief to the burning sensation in the skin, and decrease of the fever. He had not continued its use through the desquamative stage, but should try its effects in future cases. He thought the disease had changed in character within a few years; at least, his own practice showed a much smaller per cent. of severe cases than formerly. He asked if the members had observed the time of incubation; he had recently had his attention called to it by two cases which pointed to a much shorter period than that mentioned in the books. They occurred in two children living in a little village some miles up the river Delaware, where there had not been a case of scarlatina for several years. The children had not left the village, nor been in company with any one from outside for several months, until they came to Philadelphia one morning, by boat, and returned the same evening. Both were attacked with scarlatina within twenty-four hours of their return. He also asked what was the custom of the members about restraining the children within doors after being apparently well of this disease. His own custom had been to require four weeks. He had just lost a little patient whom its parents took out, contrary to his directions, two weeks after the desquamative stage was over. The day was not inclement, yet the child was immediately worse, and died within a month. He thought the child so well that he did not examine the urine before the exposure, and therefore could not say that it was the sole cause of death.

Dr. Hatfield said it was exceedingly difficult to ascertain the exact time of reception of the poison. He could recall two recent cases in which the time was supposed to be known. They were in the same family, and both exposed together. One was attacked with fever five days, the other not until twelve days, after. Supposing the second took the disease from the first, and not from the original exposure, the time of incubation would be nearly the same in each.

Dr. Hall said he remembered three cases occurring in the same family, where they were at-

tacked successively, with intervals of twelve days. There was no communication with any one outside the family after the first was attacked.

Dr. Stone thought that prophylaxis was not sufficiently appreciated by the public, or insisted upon by the physicians. The mortuary reports show scarlatina to be more deadly than smallpox, yet it did not create the same alarm. The consequence was that when the doctor gave the proper directions they were not followed, even in families otherwise intelligent.

Dr. Sauter remarked that it would be impossible to judge of the value of any method of prophylaxis without a very large number of observations, on account of the apparent capriciousness of the contagion. He attended a family only a short time ago in which this was remarkably illustrated. There were four children, three of whom were attacked successively with the anginose variety of a most malignant type—all dying. The fourth child remained in the room during the entire sickness of the others, part of the time occupying the same bed with one of them, yet did not have a single symptom of the disease. There was no attempt at prophylaxis. He would say that the family were not only poor, but refused hospital treatment and all available means of isolation.

Pigmentation of the Face in Chronic Abdominal Affections.

Dr. N. Gueneau de Mussy (*Revue Médicale*, February, 1879, quoted in the *British Medical Journal*) says that, twenty years ago, in a work on the cause and treatment of phthisis, he pointed out the coexistence of pigmentary patches on the face with abdominal tubercle. Since then the two conditions have been so constantly associated that he now regards the one as a sign of the other. Tubercular disease of the abdominal viscera is usually indicated by functional troubles, which deprive the pigmentation of any diagnostic importance, but not always; and this pigmentation may become of value. It forms bronzed patches, which usually commence in the temporal fossa, and then spread over the forehead, where they may cover the greater part, or lose themselves in a diffused coloration, like that of mulattoes. Sometimes they invade other parts, the nose or the malar region; and they may even appear on other parts of the body, particularly the backs of the hands, and are sometimes so extensive as to constitute a species of Addison's disease. Pigmentation is found in other abdominal affections besides tuberculosis. Dr. Gueneau de Mussy has met with it in four cases of cirrhosis with ascites, and in a case of cancer of the stomach; it is present also in the well-known pigmentation of pregnant women, and may last several months after confinement should anything interfere with restoration to health. It is to be distinguished, however, though often coupled with it, from the greenish-yellow tint not uncommon in abdominal phthisis, and which appears to be associated with fatty degeneration of the liver; and if by its objective character this pigmentation put on the aspect of the melanoderma described by Addison, if in some cases, by its extent, it take this disease as its model, and appears in, indeed, an early stage, it may well be asked if it have not some pathogenic connections with Addison's disease, if it do not own the same cause, acting with less energy. Dr. Gueneau de Mussy then passes in quick review the causes of Addison's disease, and concludes that all excess of pigment is developed under the same pathogenic condition; and this is a lesion or irritation of the nervous threads which form part of the suprarenal capsules, and form plexuses in their vicinity. All irritation or lesions of these nerves, in whatever part of the abdomen they commence, will end in the same result. Clinical observation is in accord with this induction. It has been seen that the most different affections, situated in all parts of the abdomen, are associated with the melanoderma of Addison's disease, or with the partial pigmentation now more particularly in question. And an irritation which is physiological and not habitual, such as that which results from enlargement and congestion of the uterus in gestation, produces the same effect, and explains the formation of the pigmentary mass which is characteristic of the pregnant state.

The Diagnosis and Treatment of Intestinal Occlusion and Obstruction.

M. Bulteau, in a recent thesis, carefully studies, one by one, 1st, the different symptoms which constitute the difference between an acute or chronic intestinal occlusion and other affections which are apt to simulate it; 2d, the pathological symptoms which may lead to diagnose the nature and seat of the occlusion. Among these symptoms are the conformation of the abdomen, the presence or absence of an abdominal tumor, the nature of the vomited matter, and the time when the vomiting sets in, the urinary secretion, etc. The second part contains a review of the different modes of treatment which have been used in this affection, such as purgatives, injections, abdominal massage, galvanization of the intestine, etc., and the author arrives at the following conclusions: 1st. In acute intestinal occlusion, if all other means have failed, gastrotomy must be performed. 2d. In chronic intestinal occlusion, either gastrotomy, or enterotomy, or lumbar colotomy, must be performed. If the seat of the occlusion should be in the large

intestine, without the precise spot being known, it will be found necessary to practice cæcal enterotomy. If, on the contrary, it should be in the sigmoid flexure or the rectum, either Littré's operation for enterotomy, or else Amussat's operation for colotomy, will be found to answer the purpose. In all other cases of chronic intestinal occlusion, according to Nélaton, enterotomy must be performed in the right iliac fossa.

Dr. Cosmo Logie gives, in the *British Medical Journal*, the notes of two cases where, by inversion of the body, serious symptoms of intestinal obstruction were overcome. One case, a young officer, apparently dying, on the tenth day of complete obstruction, was placed with his buttocks on a pile of cushions, his head and shoulders being dependent. In this position a copious oil and water enema was administered, and the whole abdomen was manipulated. In a few minutes the patient was relieved and out of danger. The second case was that of a gray-headed black, who was, at the time of the Indian mutiny, strung up by the heels and jolted up and down by his native doctor, with such good effect that, although the case had been pronounced hopeless by the army doctors, yet the patient followed on the march the next day.

Jaborandi in Puerperal Convulsions.

At a meeting of the Obstetrical Society of New York, Dr. Gillette related the history of a case of puerperal convulsions, in which jaborandi seemed to exert almost a specific beneficial effect. He first saw the patient late in the second stage of labor. She was suffering from intense headache, her face was flushed, her eyes were almost strabismic, and convulsions seemed threatening. Chloroform was at once administered, but just as the head passed the perineum she had a very serious convulsion, and from that passed into coma. He bled the patient about ℥ xij., but shortly after the bleeding another convulsion occurred; chloroform was renewed, and an attempt was made to establish diaphoresis, after administering a stimulating enema which produced a slight discharge from the bowels. The patient was wrapped in flannel blankets wrung from hot water, and was surrounded by bottles filled with hot water. A half drachm of the fl. ext. of jaborandi was given, and in about twenty minutes profuse perspiration appeared. Immediately upon the appearance of the diaphoresis, the patient came out of the coma. At the end of about two hours another convulsion occurred. The jaborandi was repeated, and diaphoresis was sustained for nearly twelve hours. No further convulsions occurred, and the patient gradually progressed toward recovery. About the tenth day after albumen reappeared in the urine, intense headache came on, jactitation ensued, and it seemed almost certain that another convulsion would occur. Jaborandi was administered; in about half an hour profuse diaphoresis was produced, the headache abated, the jactitation ceased, and the patient was soon perfectly comfortable. The same experience was repeated twice afterward. Dr. Gillette thought that the chloroform used at the beginning was not the curative agent altogether, for the reason that the jaborandi was so efficient when given alone, and so many days subsequent to delivery. In this case the remedy did not produce salivation.

Iodoform as an External Antipyretic.

In an article in the *Deutsche Medicin. Wochenschrift* for June 7th, Dr. Colsfeld, of Bremen, describes a case in which he accidentally found that the external application of iodoform was followed by a lowering of temperature. The subject was a phthisical patient, whose temperature had risen to 103.4° Fahr. He complained of troublesome, ill-defined pain in the left front of the chest, for the relief of which, other means having failed, iodoform collodion (having a strength of 33.3 per cent.) was applied. The next day the temperature had fallen to 98.6° Fahr., and the pain in the chest had entirely disappeared. The iodoform was then omitted, and the temperature again rose; but it fell when the iodoform collodion was reapplied, the strength now used being ten per cent. The odor being unpleasant, the patient discontinued the application for two days; but the febrile symptoms set in so energetically that he again had recourse to it, with marked relief. Dr. Colsfeld says that he did not observe any ill effects to be produced by the application of the iodoform, but he thinks that the expectoration was reduced in quantity. He does not pretend to say that the application would be useful in reducing the febrile process in the purely inflammatory affections of the lungs, pleura, peritoneum, etc.; but he suggests that it might be tried. The author refers to the observations of Binz, who found that the internal administration of iodoform had the effect of reducing the respiration, pulse and temperature, in a cat.

The Expectant Plan in Chorea.

Dr. Tuckwell, of Oxford, recites the following case, illustrating this plan (*Lancet*, July 5):—

Its duration, severe though it was, will be seen to correspond singularly with the average duration of chorea treated by all kinds of medicines, as estimated by Hillier and Sée—"about ten weeks" and "sixty-nine days."

A. C——, a boy aged 10 years, was admitted on March 31st, 1877, suffering from a first attack of chorea, which had begun three weeks before admission, without any assignable cause. No history of rheumatism could be traced, either in the boy or his relatives. The chorea was very severe and general. The cheeks, tip of the nose and lips were reddened and excoriated, from friction against the pillow and constant spasmodic movements of the lips. No cardiac murmur could be detected. Pulse 100; evening temperature 99°. The boy was placed in a large crib, well padded round with pillows. He was ordered to be fed every two hours with milk, eggs, and light puddings; a little minced meat and mashed potato to be taken twice in the twenty-four hours; no stimulants; no medicine.

April 7th. No improvement, but rather an increase in the severity of the spasms. The lips were fissured, and the cheeks and nose badly ex-

coriated. The pulse had ranged from 90 to 110, and the temperature had never exceeded 99°. No cardiac murmur had been heard, though often listened for. He had been well nursed and steadily fed. The bowels had acted, and the urine had been passed naturally.

9th. A remarkable subsidence of the choreic movements had taken place in the past twenty-four hours. There had been a natural sleep of some hours.

23d. Since the last note the chorea had steadily abated. The boy was quiet, and sleeping and eating well. He was, however, quite unable to speak, and when spoken to grinned in an idiotic manner. He was also partly paralyzed in both his legs, so that he could only move them slowly in bed, and could not stand upright. He passed his urine and fæces involuntarily. His temperature had kept normal, and his pulse had fallen to 80. Ordered to continue nourishment as before; no medicine.

30th. He was now able to hold his urine and fæces, and pass them voluntarily. He could speak, and had a more natural expression. He was regaining power in his legs. The chorea was scarcely noticeable.

On May 17th he could talk well, stand and walk about the ward with a little help; and on the 22d the chorea had disappeared. He could walk strongly, and talk naturally. He was discharged to the Convalescent Home at Heading-ton.

Duration of chorea before admission, three weeks; in hospital, seven weeks and three days; total duration, ten weeks and three days.

The Treatment of Vaginismus.

Dr. M. T. Gallard, of Paris, gives the following treatment for vaginismus (translated in the St. Louis *Courier of Medicine*): If there is redness or excoriations of the mucous membrane, I give the preference to iodoform, and formulate thus the ointment to use:—

		Grams.	
℞.	Iodoformi,		
	Ol. theobromæ āā	2	ʒss
	Axungiæ recentis,	15	ʒiv. M.

If there is only pain, without any apparent alteration of the mucous membrane, I prescribe—

		Grams.	
℞.	Ext. belladonnæ,	3	gr. xlv
	Axungiæ recentis,	15	gr. xlv. M.

In either case I direct to be made plugs of charpie, as small as they choose, to commence with, and in order not to frighten the patient, I charge her with the making of them, instructing her to count the threads which enter into each of these plugs, to be introduced into the vagina each night, after being anointed with one or the other of the two ointments mentioned above. If at first she uses the iodoform, she will be able, after a few days, to replace it by the belladonna, when the redness and excoriations or the eruption of the vulvar region has disappeared. Only, in either case, care must be taken to increase each day, by an imperceptible amount, but previously determined, the number of threads employed, 10, 12 or 15, for example. So we shall secure, after a time, which will never be very long, the use of a plug of such size that, after having removed it, the place may be supplied by the virile member without the substitution causing any pain." He attributes the cure in these cases chiefly to the narcotic action of the unguents applied, though not denying that there may be advantage in the mechanical effect of the dilatation also.

He utterly condemns all use of the knife in such cases, unless, possibly, when the caruncule myrtiformes are inflamed, swollen or ulcerated, when he would sometimes admit the ablation of these as a more speedy mode of cure than treatment by caustic only.

He observes that these cases are usually met with in young women newly married, or shortly after the first sexual approaches; and that they occur specially in those predisposed to hysteria and of a lymphatic temperament.

On the Duration of the Life of the Fœtus in Utero after the Mother's Death.

This question has been carefully investigated by C. Garezky, in his inaugural dissertation, St. Petersburg, 1878. He has collected 379 cases, in which the Cæsarean operation was performed after death; 308 infants were extracted dead, 37 showed signs of life, 34 were born alive; but of these, only five remained alive for some time. The author then gives a sketch of Breslau's experiments on animals, and sums his conclusions up as follows: 1. The fœtus undoubtedly survives the sudden death of the mother. 2. If it can be extracted in the course of the first six minutes, it may be born alive. 3. Six to ten minutes after the mother's death the child may still be alive, though slightly asphyxiated. 4. Ten to twenty-six minutes after death the infant is highly asphyxiated. 5. In a great many cases the infants are either highly asphyxiated or dead after the first minute. 6. The shorter the time is which elapses between the cause of the mother's death and the ceasing of the cardiac action, the longer the fœtus remains alive. 7. If the mother's death have been caused by some quickly acting poison, the chances for the child's life are greater than when it has been brought on by some other cause.

Iodoform in Chancres.

Dr. A. Sheen writes to the *Practitioner*:—

Mr. B. Hill, in his "Student's Manual of Venereal Diseases," published recently, says: "All chancres are best treated with iodoform: under its use healthy sores heal rapidly, creeping sores generally cease to spread, and sluggish ones take on healthy action." My own experience supports this statement most fully. I cannot explain the manner in which it acts, but that it does have a most remarkable effect in promoting the healing, not only of ordinary chancres, but of many other sores, I can have no possible reasonable doubt. It is what I might call a reliable remedy, and often saves one a deal of trouble. Its effects seem almost magical. You sprinkle a little of the crystals, powdered or unpowdered, over the sore, cover this with a bit of dry lint, or vaseline spread on lint,

and at your inspection next day you find that healing has progressed rapidly, the sore has filled in considerably if it is a deep one, there is but little discharge and no smell, and you have only to repeat the dressing, and so go on from day to day until healing is complete. The relief from pain is often remarkable.

The Use of Atropia in Tetanus.

In the *Lancet*, July 12, Surgeon D. H. Cullimore describes the case of a soldier who had his great toe mashed by a horse, and amputated. Symptoms of tetanus followed. Surgeon C. proceeds—

As this was the fourth case that came under my notice in the space of six months, one of which was treated with chloral, and the others with hypodermic injection of atropia in combination with morphia, and as all three terminated fatally between the ninth and twelfth day, I felt convinced that chloral would prove a failure, and, judging from the physiological effect of morphia and atropia, which are the reverse of each other, at least in so far as their action on the pupil is observed, I determined to try atropia alone, more with the object of noting its action than with any but a vague hope that it might be the means of preventing a fatal issue. On the first appearance of the symptoms one-sixtieth of a grain of atropia was injected hypodermically over the dorsal spinal region, and was repeated three times daily. On the morning of the second day one-fortieth of a grain was injected every four hours, and continued for six successive days, till the spasms had entirely ceased, and the stiffness disappeared from all but the muscles of the neck and face, which, as they were the first to become affected, continued longest under the influence of the disease. On the eighth and ninth days the dose was reduced to one-sixtieth of a grain twice a day, and subsequently reduced to one-sixtieth of a grain at night, for a further period of two days, ending on the evening of the eleventh day from the commencement of the disease, when the patient, though not yet cured, was well out of danger and in a fair way to recovery.

I should have mentioned that the bowels were constipated throughout, and were acted upon by four grains of calomel, with forty grains of compound jalap powder, administered every other day, and that after each evacuation the patient invariably expressed himself "much lighter" and relieved.

Under the influence of tonics and nourishing diet, with an occasional purgative, such progress was made that on the twenty-sixth day from his admission into the hospital, and on the twenty-first from the manifestation of tetanic symptoms, the man was discharged. During his stay in the hospital, and within the space of nine days, two grains of atropia were introduced into his system, which caused neither dilatation of the pupil nor any continued increase of temperature; in fact, there was no ascertainable physiological action, with, perhaps, the exception of drowsiness and slight occasional hyperæsthesia of the surface, which I am now more inclined to connect with the disease than the remedy.

On Traumatic Ruptures of the Heart.

In considering these injuries, M. Terrillon, in *Le Progrès Médical*, states that fractures of the ribs, driving inward of the sternum, and the penetration of missiles, are the ordinary causes of traumatic cardiac ruptures; three sorts of lesions may be thus produced:—

1. More or less extensive rupture of the cardiac walls, with death rapidly ensuing.

2. Contusions and ecchymoses of the heart's muscle; these, at certain parts of the organ, do not seem to exert any influence on its movements.

3. An internal rupture of a valve, of the cords, pillars, or even the septa, may take place. These lesions may for a certain time leave the functions of the heart intact.

The following cases are brought forward:—

1. Prescott Hewett. The patient was twelve years of age, and died four hours after a fall. An examination showed an ecchymosis, and slight tear.

M. Terrillon considers the mode in which these ruptures are brought about. If the injury is received during the systole of the heart, the state of contraction predisposes the rupture to take place at the point struck, probably the ventricular wall, but the shock, if of sufficient force, may also be communicated to the pillars and septa, and cause there, also, a solution of continuity. If the force be applied during the stage of diastole, the cavities of the organ are filled with blood and communicating, so that the eccentric compression would produce a tear in the resisting valves or the septum; hence a rupture of these parts, with no, or at most very slight, traces of an ecchymosis of the cardiac walls.

Poisoning by Veratrum Viride.

This subject, recently quite fully discussed in this journal, receives additional light from an account by M. Thiery, in a French veterinary journal, quoted in the London *Medical Record*, of July 15.

Two cows and a mule ate a quantity of fresh veratrum viride. Both cows died, one in two, the other in four, weeks. The symptoms were diarrhœa, with violent straining, by which, three or four days later, only a little blackish, glairy matter was expelled. The abdomen was inflated; the animals were very much depressed at times; the pulse, up to the end, was slow, weak, and intermittent. The pulsations of the heart were feeble, and after five or six pulsations the heart generally stopped beating for a time, equivalent to a pulsation and a half. The animals grew gradually, but persistently, thinner; milk was secreted up to the last day, but in very small quantities. At the post-mortem the following changes were found in the bodies. A few red spots in the small intestines, an ecchymosis, with several ulcerations, near the pylorus, and numerous ecchymoses in the heart, especially in the left ventricle, beneath the endocardium and pericardium. The other organs were healthy, but it is very much to be regretted that the nervous system had not been examined.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——Dr. W. J. Hoffman has published, through the Department of the Interior, U. S. Geological Survey, a study of a skull found in the Chaco Cañon, New Mexico, belonging to the ancient race of cliff dwellers. It is an interesting contribution to ethnography.

——The precautions requisite in the administration of ergot, is the subject of a reprint by Dr. J. W. Compton, Evansville, Indiana. We do not notice among the contraindications he specifies any that have not already been urged by previous writers. No doubt the drug is sometimes given when it does more harm than good.

——The report of the Board of Health of the city of Reading fills an octavo of 100 pages. It is carefully prepared, and highly creditable to the Board and its President, Dr. W. Murray Weidman. Much complaint is made of the lethargy of the city officials in carrying out sanitary recommendations.

——The North Carolina State Board of Health has published in convenient pamphlet form a series of directions for performing post-mortem examinations. They are adapted from the German regulation of 1877, and prepared by Dr. Thomas F. Wood, Secretary of the Board. By many they will be found useful and complete.

——Dr. J. W. Singleton, in a reprint from the St. Louis *Medical Journal*, pays a well merited tribute to the brave and ill-fated physicians who fell before the epidemic of yellow fever in the Southwest last year. It is entitled, "Medical Heroism of 1878." He ought to have added a full list of their names, and place and date of death.

——In an interesting paper by Dr. Swan M. Burnett, of Washington, D. C., he gives the results of an examination of the color sense of 3040 children in the colored schools of the District of Columbia. It appears that the colored race is less liable than the whites. Magnus found in 3273 white boys 3.27 per cent. to be color-blind; while Burnett, in 1349 colored boys, ranging from full-blood black to three-fourths white, only 1.6 per cent. color-blind.

——The *Transactions* of the South Carolina Medical Association, twenty-ninth annual session, April, 1879, make up a pamphlet of eighty odd pages. It contains the minutes of the proceedings at the session, and in an Appendix a number of scientific papers read before the Association. Those of most general interest are Dr. T. G. Simons' "Observations on the Yellow Fever Epidemic of 1878," and Dr. Francis L. Parker's "Statistics of 131 Cases of Stone in the Bladder in South Carolina."

——A study of the limit of perception of musical tones by the human ear, is to be found in a reprint by Dr. Laurence Turnbull, of this city. His original experiments prove that increasing age surely diminishes the acuteness of perception of tones. This diminution, he believes, is not due simply to senile thickening of the membrana tympani, but also to a gradual narrowing and change of shape in the auditory meatus, together with alterations in the middle ear, diminution of conducting power of the bones, and diminished susceptibility of the auditory nerve, incident upon advancing years.

BOOK NOTICES.

Summer and its Diseases. By James C. Wilson, M.D. Philadelphia, Lindsay & Blakiston. Price 50 cents.

This is one of the American Health Primers, and comes a little late to be seasonable, but welcome for all that. It contains a great many suggestions that the public can profitably read and remember. At the same time, it perpetuates certain faults almost always found in this class of books. To illustrate: of what earthly use is it to tell the public that in diarrhœa the treatment is "simple evacuant remedies, such as castor oil with rhubarb, or, if there be any acidity of the matter vomited or the stools, rhubarb and magnesia, followed by astringents, such as bismuth, chalk mixture and brandy, or pepsine," etc. Either give specific directions or omit the topic altogether. Such vague generalities can do no good and may do harm. These useless directions are frequent in the book. We mark one rather amusing error for a writer who discourses so enthusiastically of the country. He attributes hay asthma to the pollen of the field corn, which he informs us (page 132), in the neighborhood of Philadelphia, comes into tassel about August 17th–23d! We suspect the author resembles the poet Thompson, writer of "The Seasons," who described so eloquently the sunrise, but was accused of being so indolent in the mornings that he never saw it.

The series of Primers is, we understand, achieving considerable popularity, and their merit is entitled to it.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Half-Yearly Compendium of Med. Science,	**2.50**
Reporter and Compendium, - - -	**7.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**8.25**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE NATIONAL BOARD OF HEALTH AND ITS DUTIES.

The National Board of Health has had the usual difficulties to contend with which every far-sighted and philanthropic scheme must encounter from well meaning ignorance and deliberate jealousy.

At first there was a great howl on its supposed infringement of "State rights." A certain class of American politicians have never learned the moral of the fable of the bundle of sticks—that strength is in union, not in segregation.

From fearing that the Board would do too much, there was a sudden bound to the opposite conclusion, that it would do too little, or nothing at all. It was applied to, to perform the work of State and municipal authorities, even to pay for doing their work; and when it pointed out that such was not its sphere of action, it was abused. The newspapers said it did nothing but print manifestoes and magnify its own greatness. The Board publishes a weekly bulletin, and this became a large stone of offence to the public press, as the reporters and correspondents seemed to think that was stealing their thunder.

Then, *quarantine*, that ugly word, brought on the Board a cartload of obloquy. It was asserted that their projects would lead to the destruction of commerce, and little short of the ruin of the nation. Nobody rightly knows what quarantine means, as its significations are various, therefore, it is at all times an alarming word, calling up visions of forty days' detention in pest-houses and infected ships.

More recently the daily editor has discovered that the Board sends out various inspectors, that it pays their traveling expenses, and even a salary besides, and this it regards as a turpitude of a flagrant description, and a sad instance of squandering the public money. How the Board could employ any better or surer means of obtaining accurate and prompt information has not been suggested.

Partly to enlighten the public on the precise position of the National Board, and especially as to its relations to local boards, the Vice President, Dr. JOHN S. BILLINGS, has written an open letter to the Sanitary Council of the Mississippi Valley. We make an extract from it:—

"It is the duty of the State and local health authorities to take the initiative in adopting rules and regulations for preventing the spread of contagious diseases. The National Board of Health has made certain recommendations for such rules, which it has printed and placed in your hands. These recommendations should be taken as indicating the minimum amount of precaution to be taken. A State or local authority may make more stringent rules than these, and if they are too stringent, even to absolute non-intercourse, this board has no power to interfere. It is only when a State or local authority refuses to take even the precaution considered indispensable by this board that we can take action legally in the matter. In the next place, I would observe that this board is not expected to do all the work of prevention, nor to pay for the doing of such work. The State and local boards should first do what they can, and then we can come to supplement their efforts—to aid and coöperate—in the terms of the law. It is, therefore, the duty of State and local authorities to keep the National Board of Health fully informed on the following points, namely:—

"1. As to what rules and regulations they have adopted.

"2. As to how far they can carry out the rules and regulations.

"3. As to what aid they think it is necessary that the National Board shall furnish, in order

that proper rules and regulations may be enforced. With regard to this request for aid, details should be given. This board cannot place money in the hands of a local board to be expended at the discretion of the latter. It must be known what the money is to be used for; whether for the hire of inspectors or police, for the purchase of disinfectants, for the erection of sheds, for the purpose of establishing local quarantine, etc."

These statements are so clear that we should suppose they would prevent any clashing between the national and local Boards.

HOW SOME "DIRTY SHILLINGS" ARE MADE BY THE PROFESSION.

A physician carries on his profession for the benefit of himself and family in the first instance, and it is proper and honorable in him to make as much money out of it as he honestly can. There are, however, certain practices which are pursued, more or less, in different parts of the country, which cannot be approved by a sound moralist; and the proof that they are known to be contrary to a safe doctrine is, that they are always conducted with an endeavor at secrecy. Several of these we shall proceed to mention.

It is notorious that certain retail drug stores in this and other cities offer practitioners a percentage on prescriptions which are made up at their counters; and it is well known also that not a few practitioners take advantage of such offers. In fact, they go further, and throw all their influence against stores where they will not be paid this percentage. Yes, we have even had reported to us, in this city, compacts made between physicians, and prominent ones, too, holding official positions in the profession, and a particular druggist, by which patients were forced to buy of this druggist only, through the use by the physician of private formulæ, known only to these parties. The charge to the patient was excessive, and the discreditable plunder thus obtained was divided between the two thie— we mean the two gentlemen.

Another plan to fleece patients has been devised by the enterprising managers of establishments devoted to surgical treatment or to the care of special diseases, as cancer, etc. These managers, who always sport the title of M.D., send circulars widely among the profession in rural districts, claiming that their establishments are admirably supplied with everything needful, and are of real benefit to most patients; and having, by these statements, and numerous testimonials, allayed doubts as to their standing, they offer a percentage on the payments made by any patient the doctor will send to them. It is in this way that many of these "institutes" manage to pay their rentals and clear a handsome profit; they suborn the regular profession by money unrighteously drawn from confiding sufferers.

How such "arrangements" are regarded by the law, is illustrated in a case recently before the court at Manchester, England. It was brought to light that a doctor made it a point to send as many persons as he could to a particular dentist to have their teeth operated on; and that for this service the dentist remunerated him with a percentage on the proceeds derived from these cases. This does not seem like an aggravated case at all, inasmuch as there was no evidence that the patients were charged above the ordinary fee; nevertheless, the judge stigmatized it as "monstrous," and discreditable to professional men.

It does not seem to us that the professional conscience in this country is sufficiently sensitive to the impropriety of making money in this way. It is improper, because it is deceitful and unfair. No physician would dare tell a patient that he was to get such a commission. The patient expects to receive advice of a wholly disinterested kind when he asks what drug store to buy his prescription at, or what establishment to patronize. In common trading such commissions are usual, and everybody knows it; but in the professions they are discreditable, and should be unknown.

Physicians have much to say of the impropriety of druggists prescribing for the sick; of their repeating prescriptions without authority; of their putting up and selling proprietary medicines; of their vending adulterated medicines; and various other tricks of the trade; but to our minds the druggists could often make strong

points against the greed of the physicians to obtain percentages, the frequent unnecessary prescribing of compounds, their dispensing and sale of medicines in their offices, and other practices not more praiseworthy. Let us try to remove this beam from our own eye before we become pressingly anxious to extract the mote from the optic of the druggist.

Notes and Comments.

Therapeutical Notes.

AGARIC IN NIGHT SWEATS.

Professor Peter says, in his lectures on the treatment of tuberculosis, that agaric is one of the most efficient drugs for curing the debilitating night sweats of tuberculosis. This use of the drug is not new; it was first mentioned by Andral, according to the U. S. Dispensatory. The dose is from 20 to 30 centigrams.

IODOFORM OINTMENT IN GONORRHŒAL ORCHITIS.

Dr. Alvarez recommends—

℞. Iodoform, 1 to 2 parts
Lard, 30 " M.

To be rubbed into the testicle. It relieves the pain in the course of an hour or two, notably abridges the duration of the orchitis, prevents consecutive induration, and does not induce salivation, like mercurial ointment. For it may be substituted elastic collodion, containing from two to six parts of iodoform to thirty of collodion.

FORMULA FOR GUAIACUM.

The repulsive flavor of this drug can be partly overcome by using the following formula, suggested by Mr. Balmanno Squire, of London:—

℞. Tincturæ guaiaci, ℥ ss–j
Glycerinæ, ℥ j–ij.

If the tincture is prepared from pure rectified spirit, the above mixture will be free from cloudiness.

PURULENT CONJUNCTIVITIS OF THE NEWBORN.

The Parisian treatment is thus described by a correspondent of the *Southern Clinic*. Reverse the conjunctivæ and apply twice daily—

℞. Argenti nitratis, 25 centigrams
Aquæ destil., 10 grams. M.

Neutralize the above immediately with—

℞. Sodii chloridi, 3 grams
Aquæ destil., 10 " M.

Drop thrice daily into the eye the following collyrium:—

℞. Atropiæ sulphatis, 2 to 5 centigrams
Aquæ destil., 10 grams. M.

Apply linen compresses, dipped in ice water, to the eyes. to be continued both night and day for several days. The compresses should be held in their position on the eyes by a bandage, to prevent the constant motion of the child from removing them.

ERYTHEMA AND PRURITUS VULVÆ.

For these affections Dr. Braun-Fernwald, of Vienna, recommends—

℞. Unguenti petrolei, 5 grams
Unguenti cetacei, 3 "
Zinci oxidi, 3 " M.

An ointment for local use.

Does a Chancre Necessarily Precede Syphilis?

This question is answered with a decided negative, by Dr. Martin P. Scott, in the *Southern Clinic*. He believes in direct absorption without resultant sore, arguing as follows:—

"With the secretions of the vagina the penis comes in contact again and again, being in a state of high vascular and nervous excitement. Could there be more favorable conditions for absorption if the mucous membrane or delicate covering of the penis is an absorbent surface without abrasion, of which there can be no doubt. If absorbed, will there necessarily be a chancre on the absorbing surface? I think not.

"Most cases of syphilis, I believe, are transmitted to women by men who have no syphilitic sore on the penis. My opinion is based upon the idea that men with sores on the penis are in no condition for the amatory collision, and none but a brute would, under the circumstances, imperil even a strumpet. It is through the infected secretions that parties are, for the most part, contaminated. Nor is it necessary that a sore or chancre should be the consequence of infection.

Euonymin as a Purgative.

A correspondent of the *British Medical Journal* writes—

I have administered euonymin extensively during the last few months, both in hospital outpatient and private practice, and have been enabled to note its action in over fifty cases. In many instances I gave it alone, as a two-grain pill at bedtime, and invariably found it to act as a purgative, though tardy in its action and apt to cause griping. My usual plan now is to give two grains at bedtime for two nights running, following it each morning with a saline purge. I found that in most cases one dose was not sufficient. The saline purge entirely does away with the unpleasant symptoms of griping.

I consider euonymin a most valuable remedy in all cases of biliary derangement, sick head-

ache, etc. I like it better than any drug I have before given for these disorders. I have not in a single instance noticed that depression which was said to follow its action.

Microscopical Appearance of Fur from the Tongue.

In a recent number of the Proceedings of the Royal Society, Mr. Butlin has a paper on this subject. He says, in every case in which there is fur on the surface of the tongue, schizomycetes are found; and Mr. Butlin even observed "a little of the glœa where no fur was perceptible to the naked eye." Thin gray fur resembles the thin gray pellicle which forms on bacterium-producing fluids. This pellicle becomes white and more opaque as it grows thicker; the fur on the tongue undergoes the same changes when deposited in unusual abundance. After cultivating portions of fur on a warm stage, several fungi were discovered, two constantly present, and these were *micrococcus* and *bacillus*. In all the author's experiments, the development of *micrococcus* went on freely during cultivation, excepting in one instance, when "so rapid a formation of *bacterium termo* took place that in the course of a few hours the whole of the fluid was clouded and obscured by its presence."

The Prevention of Infantile Ophthalmia.

A writer in the *British Medical Journal* advises as follows, in order to prevent the ophthalmia of new born children:—

The instant the head is born, and before the child has time to open its eyes, I wipe away from the eyes every trace of moisture. In this way the entrance upon the conjunctiva of all acrid discharge from the vagina is prevented. I have attended to this point in hundreds of cases, and have never known it to fail; while, in the same period, ophthalmia has repeatedly occurred in those cases where the child has been born before my arrival. Carefully to wipe the eyes of the child at the earliest possible moment has now become with me so much a point of routine that I never omit it, even in forceps cases, or in the uncommon presentations, and the result is the absence of the disease alluded to.

A New Vegetable Neurotic.

The barks of one of the *Apocynaceæ* the *Aspidosperma quebracho*, a native of Brazil, has been found by Dr. Penzoldt, of Erlangen, to be quite useful in dyspepsia depending on emphysema, bronchitis, phthisis, pleurisy, etc. A teaspoonful of a solution was given two or three times a day. The most marked objective phenomenon after its exhibition was a reddening of the previously cyanosed or livid tint of the lips and face. The respirations generally became deeper and less frequent, and the patients expressed themselves subjectively much relieved. The first feeling after taking the drug was one of warmth in the head; many said that they had less desire to cough, and that they found expectoration easier. Occasionally sweating occurred, and in some cases abundant salivation. No bad effects were noticed.

Correspondence.

The Decimal System.

Ed. Med. and Surg. Reporter:—

The idea of simplicity in the decimal system as applied to medicine has not been sufficiently illustrated. Look at it a moment. Call grams dollars, parts of grams cents, and nothing can be plainer. To translate the old system into the new, all we have to do is to remember that one grain or one minim equals 06, or six cents; one dram equals 4.00, or four dollars; one ounce equals 32.00, or thirty-two dollars. Now, let us do a little translating:—

	Old System.			New System.	
℞.	Strychniæ sulph.,	gr.j	=	06	
	Sacch. alb.,	ʒij	=	8	
	Acid acetic,	gtt.ij	=		12
	Aquæ dest.,	℥ij.	=	64	
℞.	Potassæ acetat,	ʒss	=	16	
	Sp. æth. nit.,	ʒij	=	8	
	Tinct. aconit. rad,	♏j	=	4	
	Syr. aurantii cort.,	♏j	=	32	
	Aquæ cin. q. s. to make	ʒiv.	=	128	
℞.	Hydrarg. chlor. mit.,	gr.xx	=	1	20
	Camphoræ pulv.,	gr.x	=		60
	Opii pulv.,	gr.xvi	=	1	
	Glycyrrhizæ pulv.,	ʒj.	=	4	M.

Divide into 20 parts.

Surely, no one possessing ordinary reasoning powers can be puzzled with this matter. Grains xvj can be written 1 | or | 96, the slight difference being non-essential.

The Oregon State Medical Society, at its recent meeting, unanimously approved of the decimal system, and requested its members to put it into immediate practice. Certainly nothing but indifference, stupidity or obstinacy stands in the way of the new system. I hope no physician will risk being charged with either of those imperfections.

Another idea. Suppose the meter is not mathematically the forty millionth part of the earth's meridian, who cares? All we want is a uniform rule; it matters not whether that rule be three feet or six feet. The unit is nothing. All we want is the decimal system of multiplying and dividing that unit, whatever it may be.

Canyonville, Oregon. C. H. Merrick, M.D.

Neuralgia—Importance of Treating the Paroxysm.

Ed. Med. and Surg. Reporter:—

Any treatment of neuralgia that does not take into prominent consideration the paroxysm, must be, to a greater or less extent, futile. Pain exhausts and depresses the vitality to such a fearful degree that it must be checked at all hazards. Especially is this true of those cases in which the neuralgia depends upon a depraved and weakened condition of the general system. I would not detract one jot from the recognized importance of the general treatment, but would simply emphasize the importance of quelling the paroxysm of pain at its very invasion. If the neuralgia depend upon a diseased tooth, for instance, it would be unpardonable folly to content ourselves with a prompt subduing of the pain, while permitting the tooth to remain. The treatment of the attack proper, and the general treatment, are necessarily and thoroughly complimentary to each other.

Generally speaking, there seems to be a tendency among practitioners to practically ignore the treatment of the paroxysm in their management of the various forms of neuralgia. Many seem never to have realized to themselves the real worth of prompt relief in such cases as the instance in question. The very first thing to be done when called to a neuralgic patient who is being racked with agony, is to employ the most decisive means at our command. The patient is not only unspeakably grateful for such telling interference, but a vast expenditure of vital force is prevented.

To lay stress upon this point may seem to some like attempting to prove an axiom; but I know whereof I speak when I say that the importance of this matter is greatly undervalued in actual practice.

Among the various remedial agents which have been used for this immediate treatment are morphia, atropia, inhalations of chloroform, aconite, Indian hemp, hyoscyamus, conium, bromide of potassium, etc. Some of this list, morphia and atropia more especially, are not merely efficient in rapidly allaying pain, but are positively curative in their action. To this fact we have the testimony of such high authorities as Bartholow, Hammond and others.

Dr. Hunter has ascertained that atropia, hypodermically injected, in sufficient quantity ($\frac{1}{50}$ to $\frac{1}{80}$ grain), has a permanently beneficial influence in tic-douloureux and sciatica. While Dr. Anstie has stated that the same remedy is particularly useful in peri-uterine and dysmenorrhœal neuralgia. Again, morphia, the most widely used of the foregoing agents to several varieties of neuralgia, may be administered (hypodermically, of course) with confident prospects of lasting good. I have recently administered it in tic douloureux, with excellent curative effect. It would seem entirely superfluous to here offer even a word of caution as to the danger of the morphia habit. A little good whisky will, in some cases, frequently abort an attack, as I have seen abundantly verified.

We are well aware, however, that many of these agents have their drawbacks; but these are insignificant when weighed in the balance with the prostration and physical depression incident to an unallayed and violent neuralgic paroxysm. Atropia, though its effect in alleviating pain is more enduring than that of morphia, has attendant upon its action hallucinations, and occasionally delirium; and this, too, when given in legitimate doses. Attendant upon the action of morphia are frequently a persistent nausea and itching of the cutaneous surface (but we must remember that this nausea frequently occurs in the course of an attack of neuralgia, even when morphia is not exhibited).

Then again, following in its wake are some very unpleasant cerebral and other effects. These, as was first showu by Bartholow, may be prevented, or at least alleviated, by a full dose of bromide of potassium. As is well known, however, the ill effect of each of these drugs (morphia and atropia) are very largely counteracted when used in combination. We find now and then a case where morphia not only fails to afford any relief, but really intensifies the agony of the paroxysm. Tanner says in such instances he finds no remedy so valuable as a mixture of atropia and arsenic (gr. $\frac{1}{60}$ of the former to $\frac{1}{30}$ of the latter), used hypodermically.

Any, or indeed all, of the objections and ill effects incident to the administration of remedies to cut short the paroxysm, we repeat, do not form the slightest argument, in the face of facts, against the course of treatment above advocated. And the physician who will be rewarded by the best results in the management of neuralgia, especially where the attacks are violent, is the one who decisively acts upon the importance of arresting the paroxysm. J. W. Hickman, M.D.

1945 *N. 11th St., Phila.*

Corporal Punishment.

Ed. Med. and Surg. Reporter:—

My attention has for a number of years been called to injuries caused by occasional cases of too severe, or recklessly executed, punishment of school children. Foremost educators, while not believing it expedient to prohibit corporal punishment, acknowledge that injury, injustice, and sometimes death even, do now and then occur from its use. These serious results may arise from fright, or from concussion of the brain, produced my merely jerking the child about, or—the most frequent cause—inflicting the punishment upon the child's head. I have known death to occur solely from the fright, although fatal results cannot likely arise except from immediate blows upon the head.

No one form of punishment is so dangerous as boxing the child upon the ear. Not only is injury to the organ of hearing often produced, but inflammation of the brain frequently follows, and death has been the result.

In the family, this matter of injurious methods of punishment is not by any means beyond our influence, if we will but take pains to inform people upon the subject.

If corporal punishment is allowed at all in schools, its use ought to be carefully guarded. No teacher should be allowed to punish a child by rudely jerking it about, by striking it any-

where upon the head, or with any instrument whatever, except it be flexible and with smooth edges. These requisites are best fulfilled by a rubber strap with rounded edges. Moreover, no punishment should be permitted except it be inflicted in the presence of a principal, another teacher, or a school trustee, as a salutary check upon undue temper or excitement. Every case of corporal punishment should also be reported in writing to the Board of School Trustees, stating the offence of the pupil and the manner and severity of the punishment. I have known the above rules adopted by a board of school commissioners to reduce the number of cases of corporal punishment eighty-eight per cent. in one month, and the schools continued meanwhile even more orderly and satisfactory than before.

I am about collecting statistics of serious and fatal injuries caused by corporal punishment, and I write this article to request all the readers of the Medical and Surgical Reporter to forward to me statistics and history of all cases that may have come to their knowledge. State the date, place, name of child, character of punishment, and its results; also the offense for which the punishment was inflicted. Add other points, history, etc., if time and inclination suggest. I urge all to give the subject the little attention needed, to write me the main facts, at least, of all cases they have known, and thereby make the report more valuable. The information thus obtained I will communicate through this journal.

Bloomington, Ill. B. P. Marsh, M.D.

[The above is timely. We have had within the last six months two cases of partial deafness under our care, both distinctly traceable to punishment by "boxing the ears."—Ed. Reporter.]

Malarial Fever.

Ed. Med. and Surg. Reporter:—

In the early stages of the ordinary forms of malarial fever it is always safest and best, from the infant up, consulting individual peculiarities, in chill, fever or sweating stage, to use without delay a combination of calomel, opium (or ordinarily I prefer it in form of Dover's powder, made with chlorate instead of sulphate of potash) and quinine or cinchonidia (I tested the cinchonidia from July 1st till November 1st, 1878, in 1500 cases of malarial fever, and in proportion of five to four of quinine, found it equally efficient).

℞. Calomel, grs. v–xv
Pulv. doveri, grs. xv
Cinchonidiæ sulph., grs. xxiv. M.

Make eight doses for an adult.

Sig.—Give one every three hours till fever subsides, in capsule or tissue paper.

This course may be steadily pursued from forty-eight to ninety-six hours, if required. On the subsidence of the fever continue cinchonidia, in three-grain doses, for forty-eight hours. If found in the intermittent stage, with but little time to go on, give all your medicine at one dose. If the stomach is very irritable, give a decided hypodermic of morphia, and go on with the preceding treatment so soon as the effect of morphia is decidedly felt; repeat at once any dose that may be vomited. If symptoms are threatening, and time is short, give a full mercurial and hypodermic of morphia, to be followed in fifteen minutes by from two to twenty grains, hypodermically, of a neutral solution (prepared with diluted sulphuric acid) of quinine, sixty grains to the ounce of water. If the attack be of a congestive character, which will rarely happen if it has been possible to pursue the course indicated, use the same combination in large quantities. If the brain be threatened, or the congestion be prolonged, bleed freely, so as to restore the equilibrium and hasten the possible action of the internal or hypodermic medication. In the hemorrhagic variety, dropping entirely and through all the treatment opiates in any form, the same course must be followed, only adding here that in this variety, where the mercurial action is most urgently required, it may be hastened by triturating the calomel, for at least ten minutes, thoroughly with brown sugar. During all the forms a saturated solution of chlorate of potash is freely used, to which may be added, if the tongue is flabby and indented, a teaspoonful of bicarbonate of soda to the tumbler of potash solution; of this one tablespoonful may be given hourly during the day. Finally, as a tonic, to assist, I have never found anything more efficient to build up than—

℞. Tinct. ferri chlorid., f. ʒ v
Fld. ext. nucis vom.,
Acid nitro-muriat.,
Liq. potass. arsenit., āā ♏c.

Mix slowly (fifteen minutes) in mortar. Tie down cork.

Sig.—Take twenty-five drops after each meal, in half a glass of water.

For the first fourteen days after relief from fever, take with each dose of this two grains of cinchonidia. After that use full doses of the antiperiodic on the recurring days. Continue tonic as required. A faithful pursuit of the above plan will certainly give about the best attainable results. Edward H. Sholl, M.D.

Gainesville, Ala.

Hypodermic Injections in Cholera.

Ed. Med. and Surg. Reporter:—

I noticed an article in the last number of your journal calling attention to the great value of hypodermic injections in cholera morbus. It may be interesting to know that this plan has met with great success in the treatment of Asiatic cholera, and is now widely used in the East. Dr. Charles M. Fisher, late of New York, now enjoying a large practice at Nagasaki, Japan, told me a few weeks since, during my visit to that country, that he treated all his cholera cases—and a year never passes without many of them—with the administration of a large hypodermic injection of morphia, either alone or associated with atropia, and that if the injection could be given as soon as the first symptoms were manifest the cases invariably recovered. Dr. Fisher's large experience and

emphatic expression of his opinions on this subject are worthy of attention.

J. M. KEATING, M.D.

Philadelphia, August 16th.

NEWS AND MISCELLANY.

The Yellow Fever.

The steady progress of the epidemic in Memphis has been less startling than last year, but for all that, sure and fatal. From 20 to 30 new cases daily, in a town so depopulated as Memphis now is, and where of those that remain so many are protected by previous attacks, is indicative of a potent and concentrated infection. Of other towns, Corinth, Miss., has had one or two cases. Mayersville, Miss., is also reported as suffering. It has been very properly decided to continue perfecting the system of isolation of Memphis, under the rules of the National Board of Health, which have already given such good results; to use every possible means to induce the negroes, who constitute the main source of danger in Memphis, to move into camps, and thus deprive the fever of material to work on; to secure the isolation of cases and affected houses, blocks and districts, and to effect this by combining as far as possible the resources of local, State and national boards with those of the Howard Association and of the taxing district and county authorities, and thus limit the spread of the disease.

Dr. W. L. Coleman, of San Antonio, Texas, who was ordered by the National Board of Health to investigate the origin of the yellow fever prevailing in Memphis, has been at work for a month past, and his investigations convince him that the germs were imported direct from the West Indies, and that they passed the New Orleans Quarantine unchallenged, and arrived in Memphis some time in June. The Howard Association had last week 207 nurses attending 196 families, 120 of whom are whites and 76 colored. Their expenses daily aggregated $900. The total deaths from yellow fever for the week ending at 6 P.M. Saturday, August 16th, were 46; to that date, 139.

A Victim of the Quinine Speculators.

Dr. D. J. Roberts, of Nashville, pays us his compliments in the last number of the *Southern Practitioner*, for what we have said on the quinine question. He has discovered that we have been paid by the quinine manufacturers to advocate the repeal of the duties on quinine and bark! Few discoveries of his can equal this. As for the terms in which he announces this discovery, they are such as we expect in the *Southern Practitioner*, the strong point of which has always been its supremacy in Billingsgate.

We pardon Dr. Roberts for his charge against us. We shall not use the *tu quoque* argument. We do not believe Dr. Roberts was paid by the drug sharps of London and New York; he was simply one of their tools, the catspaw they used to pull their chestnuts out of the fire; and we suspect his rage at us is because he is waking up to this not pleasant fact. We pity him.

Organization of the U. S. A. Medical Department.

According to the Act passed by the last session of Congress, the Medical Department of the Army will hereafter consist of one Surgeon General, one Assistant Surgeon General, one Chief Medical Purveyor, four Surgeons, with the rank, pay and emoluments of Colonels, two Assistant Medical Purveyors, eight Surgeons, with the rank, pay and emoluments of Lieutenant Colonels, fifty Surgeons, with the rank, pay and emoluments of Majors, and one hundred and twenty-five Assistant Surgeons, with the rank, pay and emoluments of Lieutenants of Cavalry for the first five years' service, and with the rank, pay and emoluments of Captains of Cavalry after five years' service.

Results of Treatment in Vienna.

There is strong reason to believe that the modern treatment of disease in Germany has greatly deteriorated since the days of Niemeyer. Theorizing, histology and diagnostic refinements have taken the place of the effort to cure disease by rational empiricism. Witness the next to worthless therapeutics in Ziemssen's *Cyclopædia*. A Vienna correspondent in the Canada *Medical and Surgical Journal* gives some striking statistics. In Bamberger's clinic, of 27 cases of pneumonia, 17 died; 24 per cent. of all cases of typhoid fever die; facial erysipelas is "frequently fatal," etc. We do not believe that the case book of the average American physician shows anything like this mortality; and our city hospitals certainly do not. It looks as if medical science in Germany was running to seed.

The Season Abroad.

England has been having an unprecedentedly cold, wet and stormy summer; nevertheless, the public health has been good, and the mortality unwontedly low. In Switzerland the South wind, the *Fohn*, has been steadily blowing, causing heavy floods and much dampness, interfering greatly with pleasure and health seekers. Neither the high resorts, as Davos, nor the low ones, as the Riviera, Nice, etc., report so well on last spring and winter as usual.

Items.

—A Constantinople dispatch says: Some cases of Asiatic cholera are reported here, but they are believed to be sporadic.

—The Atlantic City *Review* is authority for the statement that Dr. Rockwell, of Aiken, South Carolina, contemplates the establishment of a sanitarium at Atlantic City.

—The New York artist, Mr. F. B. Carpenter, has finished a nearly full-length portrait of Dr. Crawford W. Long, late of Athens, Ga., who used ether to destroy pain in surgical operations March 30, 1842, nearly three years before Horace Wells discovered that nitrous oxide gas was also an effective agent to produce a similar result, and more than six years before Sir James Y. Simpson demonstrated that chloroform was as effective.

American Otological Society.

At the annual meeting of this Society, held in Newport, R. I., July 22d, the following officers were elected for the ensuing year: President, Dr. A. M. Buck. Vice President, Dr. Charles H. Burnet. Secretary and Treasurer, Dr. J. J. B. Vermyne. Publication Committee, Dr. J. O. Greene, Dr. Clarence J. Blake, and Dr. Vermyne. Committee on Membership, Dr. George Strowbridge, Dr. H. D. Noyes, and Dr. C. J. Blake.

Personal.

—Dr. Alban S. Payne, of Markham, Fauquier Co., Va., has been elected Professor of Theory and Practice of Medicine in the Southern Medical College of Atlanta.

—Dr. E. S. Gaillard, editor of the *American Medical Biweekly*, has severed his connection with the Kentucky School of Medicine at Louisville.

—Dr. H. M. Paine, of Albany, N. Y., writes us that his name appears as one of the curators of the "modern school," Homœopathic Medical College, Buffalo, "without his knowledge or approval."

—We have to chronicle another medical Governor. Dr. Robitaille (M.D., McGill College, 1860) has just been named Lieutenant Governor of the Province of Quebec, in place of Lt. Gov. Letellier de St. Just, removed.

OBITUARY NOTICES.

—Dr. Edwin D. Morgan, Jr., son of ex-Governor Morgan, of New York, died at Suffield, Connecticut, on Friday. His health has been delicate for some months.

—Dr. Charles Rowland, of Brooklyn, who died August 9th, of paralysis, was born in Fairfield, Ct., in 1800, and graduated at the Yale Medical School in 1824. In 1825 he began to practice in Brooklyn, where he afterward remained.

—Dr. Adam E. Wright, a well known physician of Wilmington, N. C., died on the 14th of July, about 46 years of age. Agreeable in conversation, and of generous impulses, he was highly esteemed in that community.

—Dr. Horace T. Porter, twenty-nine years old, died suddenly, Aug. 14th, at his residence, in this city. He was a graduate of the University of Pennsylvania and a member of the Medical Boat Club of West Philadelphia.

—The death of Dr. Samuel Brown Wylie Mitchell, in the 55th year of his age, took place Aug. 16th. Dr. Mitchell was well known in Philadelphia, though he was less prominent as a physician than as a military and society man. During the war he took an active part in the defence of the country, and became brevet-colonel of United States volunteers. For some years, also, he served in the capacity of surgeon at the Philadelphia Navy Yard. Dr. Mitchell was a man of wealth and position, and his decease will be regretted by many friends.

QUERIES AND REPLIES.

Dr. J. L., of Ohio, asks: Is there any remedy for gall stones? Several valuable remedial measures will be found in Napheys' *Medical Therapeutics*, sixth edition; in fact, all that have any strong evidence in their favor.

Dr. F. L., of Maine.—It is, we believe, a fact that the skin of creoles and other natives of tropical climates is cooler than that of residents in cold latitudes; but we cannot find any thermometrical observations on the subject.

Dr. Ricardus, of Pa., writes: "There is a belief quite general among the people of this locality that eating tomatoes to excess produces jaundice. Is there any foundation for it?"

Ans.—We cannot recall any medical statements to this effect. Several cases have been published in the English journals, of "simulative scarlet fever," from eating tomatoes. Any reader who can give information as to bad results from their consumption will oblige us by doing so.

Legens.—The medical law in this State (Pennsylvania) is practically inoperative.

MARRIAGES.

AMICK—TAYLOR.—At the residence of the bride's parents, "Gold Hill Farm," near Chapman, Dickinson county, Kansas, July 23d, 1879, by the Rev. Elijah Clark, Dr. M. L. Amick, of Cincinnati, O., and Miss Maggie Taylor, daughter of John Taylor, formerly of Cincinnati.

BERLET—WALTER.—On Wednesday, August 6th, 1879, by the Rev. John Thompson, at the residence of the bride, James F. Berlet, M.D., and Margaret E., Walter, all of Philadelphia.

BRODIE—KRAUSE.—On July 30th, by the Rev. F. P. Bender, William B. Brodie, M.D., and Emma C., daughter of Charles B. Krause, all of Philadelphia.

CLEVELAND—CONOVER.—In this city, on August 14th, at the First Unitarian Church, by the Rev. W. H. Furness, Samuel M. Cleveland, M.D., and Julia H., daughter of the late William A. Conover, of Freehold, N. J.

LAWRENCE—STUART.—In Pittsburg, on the 21st ult., by the Rev. Charles C. Thompson, D.D., Dr. E. S. Lawrence, of Philadelphia, and Miss Jeanie L. Stuart, only child of the late A. J. Stuart, of Pittsburg.

LIGGETT—ADDY.—On July 30th, by Rev. Thomas R. List, Samuel J. Liggett, M.D., of Philadelphia, and Miss M. E. Addy, of Leeds, England.

MELLERSH—HUMPHREYS.—On Thursday evening, July 31st, at the residence of the bride's parents, by the Rev. George W. Anderson, D.D., Dr. A. H. Mellersh, of Merion Square, Pa., and Miss Clara M., daughter of Seth Humphreys, Esq., of Lower Merion, Pa.

MERRILL—SIMPSON.—In New York, on Monday, August 11th, by the Rev. Edward O. Fladd, D.D., John N. Merrill, M.D., and Miriam Simpson, daughter of George Simpson, Esq.

DEATHS.

HOUTZ.—In Canal Fulton, Ohio, on July 27th, of obstruction of the bowels, Dr. Abram Houtz, in the 57th year of his age.

LEAVITT.—In Trenton, N. J., on the 12th ult., Robbie, son of Dr. Lyman and Martha B. Leavitt, aged 6 months.

PETERSON.—In this city, on the 23d ult., Blanche, wife of Dr. Robert E. Peterson.

READ.—On the 28th ult., Dr. Zachariah Read, of Mount Holly, N. J., in the seventy-first year of his age.

TAMAR INDIEN,

A laxative, refreshing, and medicated Fruit Lozenge, agreeable to take, and never causing irritation. Its physiological action assures the immediate relief and effectual cure of

CONSTIPATION, CEREBRAL CONGESTION, HEADACHE, INDIGESTION, BILE, HEMORRHOIDS, etc., etc., by augmenting the peristaltic movement of the intestines, without producing undue secretion of the liquids. Unlike pills and the usual purgatives, it does not predispose to intestinal sluggishness, and the same dose always produces the same effect, that is to say, never needs increasing. These properties render "Tamar" invaluable to the weak and debilitated, and especially to ladies previous and subsequent to their accouchement. It is recommended by the most eminent Physicians of Paris; notably Drs. BELIN and TARDIEU, who prescribe it constantly for the above complaints, and with most marked success.

Prepared by **E. GRILLON,** Pharmacien de lère classe, 27 Rue Rambuteau, Paris. To be had of all respectable Chemists throughout the world.

PEPTODYN.

The New Digestive is a combination of the whole of the Digestive Secretions—Pepsine, Pancreatine, Diastase, etc.,

Forming an invaluable remedy in the treatment of all forms of Dyspepsia, and diseases arising from imperfect nutrition.

N. B.—*The success of this Remedy has led to several imitations of it,* which consist largely of Milk Sugar, and, as compared with Peptodyn, are of little or no real value as digestive agents.

SAVORY & MOORE, 143 New Bond Street, London.

PARIS, 1867. Prize Medal.

1868. Silver Medal.

1872. Gold Medal.

1873, VIENNA. Medal of Merit.

BOUDAULT'S PEPSINE

IN POWDER, also WINE, ELIXIR, SYRUP, PILLS, AND LOZENGES OF PEPSINE.

Since the introduction of Pepsine by Boudault in 1854, **BOUDAULT'S PEPSINE HAS BEEN, AND IS STILL CONSIDERED, THE MOST RELIABLE,** as is attested by the awards it has received at the Exhibitions of 1867, 1868, 1872, 1873, and in 1876 at the Centennial Exposition in Philadelphia.

IT IS THE ONLY PEPSINE USED IN THE PARIS HOSPITALS.

Careful tests will enable any one to satisfy himself that **BOUDAULT'S PEPSINE HAS A DIGESTIVE POWER AT LEAST DOUBLE** that of the best Pepsines in the market, and that it is really the cheapest.

It is Sold in 1 ounce, 8 ounce, and 16 ounce Bottles.

Beware of so-called French Pepsines bearing fictitious names, and prescribe Boudault's only.

BLANCARD'S PILLS

OF UNCHANGEABLE IODIDE OF IRON.

Blancard's Pills of Iodide of Iron are so scrupulously prepared, and so well made, that none other have acquired a so well deserved favor among physicians and pharmaceutists. Each pill, containing one grain of proto-iodide of iron, is covered with finely pulverized iron, and covered with balsam of tolu. Dose, two to six pills a day. The genuine have a *reactive silver seal* attached to the lower part of the cork, and a green label on the wrapper, bearing the fac-simile of the signature of

Blancard

Pharmacien, No. 40 Rue Bonaparte, Paris

without which none are genuine.

BEWARE OF IMITATIONS.

E. FOUCERA & CO., Agents,

NEW YORK.

NEW REMEDIES.

RECENTLY INTRODUCED BY US.

RHUS AROMATICA.

Highly recommended in the treatment of diabetes and other diseases of the genito-urinary organs, viz.: Hematuria, enuresis (in both old and young), uterine hemorrhage, and as a local application in leucorrhea; also in atonic diarrhœa and dysentery, and more especially summer diseases of children.

See article by Dr. McClanahan, in the April number of *New Preparations.*

We offer this new remedy in the form of a fluid extract from the fresh bark of the root.

FOLIA CAROBÆ.

JACARANDA PROCERA (SPRENGEL). This new drug, from Brazil, is now attracting the attention of the profession in Germany, as a valuable and effective anti-syphilitic. It is said to possess alterative, diuretic, sudorific and tonic properties, to a marked degree, especially in the latter particular. Hence its application to the treatment of syphilis in all its forms.

The Carobæ may be continued advantageously with Iodide Potassium in cases distinguished by pains in the limbs. It is indicated in the cure of old syphilitic ulcers, to which it may be applied topically.

CASCARA SAGRADA.

RHAMNUS PURSHIANA. This is the bark of a tree indigenous to northern California and Oregon, known botanically as the Rhamnus Purshiana. It has long been used on the Pacific Coast, among the Indians and old Spanish residents, as a remedy for habitual constipation and other disorders of the alimentary canal. Many physicians write to us that they must have the Cascara *at any price*, as it has proved invaluable in their practice.

We cannot too strongly caution physicians and druggists to specify "**P., D. & CO.'S,**" if they desire a preparation of the *true* drug, Rhamnus Purshiana.

COTO BARK.

The tree from which this bark is derived is a native of Brazil and Bolivia, though as yet we *cannot locate it botanically*. Coto Bark was first tested clinically by Prof Gietl, of Munich (Germany), who considered it a specific for diarrhœa in its various forms. Dr. Riecker, of Stuttgart, concurred in this. Prof. Baetz, of Tokio, Japan, in the *Centralblatt*, recommends it for malignant cholera In Bolivia it is used for diarrhœa, colic, and neuralgic toothache, and externally in rheumatism and gout. It has been also employed in the sweating of phthisis, and typhus, catarrhal diarrhœa, gastric catarrh, pneumonia, uterine colic, acute articular rheumatism, cholera, cholera morbus, dysentery, night sweats, etc.

FIVE FLOWERED GENTIAN.

GENTIANA QUINQUEFLORA. Among the many substitutes for quinine this plant is one of the most valuable. In many cases where quinine and other antiperiodics have proved futile, this remedy has been found very efficacious. In combination with hydrastis, it has been found an excellent tonic in depraved conditions of the digestive apparatus, increasing the bilia y secretions and acting as a stimulant to the excreto y organs. In fevers, in combination with gelsemium, and in derangement of the biliary organs, in conjunction with leptandrin and podophyllin, it seems to increase the action of those agents.

GRINDELIA ROBUSTA.

This remedy has been successfully employed in asthma, bronchial difficulties, iritis, vaginitis, and other diseases of the mucous surfaces. In combination with Yerba Santa it has also been found specially efficacious in bronchial affections. It is well known that many of the varieties of this family bear so close a resemblance to each other that it is difficult to distinguish between them, and the Squarrosa and other varieties are hence often unwittingly substituted for the Robusta. Our own supply is gathered for us under the direction of a competent botanist, and is known to be genuine.

DESCRIPTIVE CIRCULARS.

We shall be happy to furnish upon application descriptive circulars giving the botanical history and therapeutical application of New Remedies recently introduced by us. We will also send, if desired, our price list, giving names and prices of nearly two thousand articles manufactured by us.

☞ *Send stamp for Price List and Circulars described above.*

PARKE, DAVIS & CO.,

Always specify Parke, Davis & Co.'s. **DETROIT, MICH.**

Our goods can be procured of Messrs. W D ELLIOT & Co., Philadelphia; LEHN & FINK and WALTER ADAMS, New York; SMITH, DOOLITTLE & SMITH, Boston; and of druggists generally throughout the West.

HINTS IN THE OBSTETRIC PROCEDURE.

BY

WILLIAM B. ATKINSON, A.M., M.D.,

Lecturer on Diseases of Children, at the Jefferson Medical College; Physician to the Department of Obstetrics and Diseases of Women, Howard Hospital, Philad'a.

SECOND EDITION. ENTIRELY RE-WRITTEN AND ENLARGED. 12MO, CLOTH. PRICE, $1.00.

The very gratifying reception given this handbook of the essentials of the obstetrical art has led the author to submit it to a careful revision, and increase its size by adding a number of new topics.

It may safely be characterized as the most convenient, compact, reliable and handy *vade mecum* on obstetrics in the language; as the following personal and editorial statements sufficiently attest.

OPINIONS OF PHYSICIANS AND THE PRESS.

"It is really a '*multum in parvo*,' and will, I am sure, be of great service to multitudes in the profession who have hitherto followed the routine of old traditions."—*Prof. Fordyce Barker.*

"It is as good for the old as for the young practitioner."—*Dr. J. Marion Sims.*

"It abounds in extremely valuable hints, and calculated to do much good."—*Prof. Goodell.*

"Founded upon the personal experience of the author it must prove of value to the very wide circle of the profession who will be led to purchase it by their acquaintance with the author and his reputation."—(Philadelphia) *Medical Times.*

SOME OBSERVATIONS UPON CHOLERA INFANTUM, ESPECIALLY IN REGARD TO ITS CAUSATION.

BY FRANK WOODBURY, M.D.,
Attending Physician to the German Hospital, Philadelphia.

The intestinal disorders of infancy having diarrhœa as a common and prominent feature, which are so frequently encountered during the hot months of the year in all of our large cities, are, in this country, not rarely grouped under the generic title of summer complaint; but our systematic writers on diseases of children distinguish at least three well-defined morbid states under this heading: 1st, Ephemeral, non-inflammatory, or simple diarrhœa; 2d, Enterocolitis of all grades of severity; and 3d, Cholera infantum. It is to the latter, viewed as a distinct morbid state, that this article invites a brief consideration, more especially with reference to its proximate cause or causes.

Before the clinical relations of a disease can be satisfactorily studied, it is essential that its own position shall be accepted, and its claim to be regarded as a distinct disorder generally acknowledged. *A fortiori*, prior to any definite statement of the causation of such an affection, there must be a common agreement as to the application of the title, *i.e.*, it must be used in a specific sense, and restricted to one meaning throughout the discussion.

This statement seems necessary, by way of introduction, since there is an unfortunate tendency to extend the name cholera infantum to a wider range of clinical application than of right belongs to it. Believing that there is a well marked morbid condition to which this term can with propriety be applied, and which without this distinctive title is liable to have some of its important features ignored, it is to be hoped that the name will not only be retained for this affection, but also, that it will as much as possible be restricted to a disease to which American writers have paid especial attention. Indeed, from the fact that such valuable contributions to its pathology and clinical history have been made by authors on this side of the Atlantic (among the pioneers being Dr. Rush, whose clinical essay was published in 1789, followed by the treatises of Miller (1800), Mann (1805), and the writings of Jackson, Horner,* Dewees, Eberle, Stewart, and Condie), it has been inferred by some English writers that cholera infantum is a disorder almost peculiar to America, or, at least, occurring here in much greater frequency than elsewhere. Dr. Condie noticed that it was more common in the Southern and Western States, chiefly in the large cities, but doubted whether the disease existed in its generic form so far east as Boston. It is now generally known that cholera infantum is endemic in all localities that present the necessary conditions for its development, which conditions will be considered further on. In the opinion of those who have had an opportunity of studying similar disorders while in London, a disease is encountered there differing in no essential features from that which we are here called upon to treat, and swelling the lists of mortality during the summer months to as great a degree as it does in this country; the only difference being that there the disease in question is not

* *American Journal of Medical Sciences*, Feb., 1829.

usually separated from similar disorders of infancy, but they are all classed as summer diarrhœa.

Dr. J. Lewis Smith, a very capable and experienced observer, says: "The number of deaths from cholera infantum reported in our bills of mortality is so large, while the number from the same disease embraced in the death statistics of European cities is so small, comparatively, that some have been led to believe that this malady is much more prevalent and fatal in this country than in Europe, whereas were these terms employed in all places to designate precisely the same disease, probably no great difference would be found in the prevalence of cholera infantum on the two sides of the Atlantic." *

That this opinion is correct is rendered evident by the tenor of a report recently presented to the Epidemiological Society, London, by Mr. George Turner, Medical Officer of Health for Portsmouth, a synopsis of which was published in the *British Medical Journal* for May 31st, 1879. In this report Mr. Turner called attention to the great mortality, particularly among infants under one year of age, occurring in large English cities, from *summer diarrhœa*, and insisted upon the close relationship which exists between a sustained high temperature and the production of this disease.

Bristowe speaks of the same affection under the title of *infantile diarrhœa*, and Rilliet and Barthez, who discuss the disorder with more thoroughness than most foreign writers, give it the name of *gastro-intestinal choleriform catarrh.* We cannot help remarking the similarity in the pathology and especially the etiology of the disease, as well as the conclusions of the report by Mr. Turner, just referred to, and those of cholera infantum, as brought prominently forward in the report on Clinical and Meteorological Records in their Relation to Etiology, presented by Prof. N. S. Davis, chairman of a committee upon this subject, to the American Medical Association, which contains original observations of real value, in regard to the etiology of this disorder; the conclusions being as follows:—

"1. That the bowel affections so prevalent, more especially in the middle and northern parts of this country, and so destructive to infantile life in the larger cities, recognized as simple diarrhœa,† cholera infantum, cholera morbus, and dysentery, begin their annual prevalence with the occurrence of the first week of continuous high summer temperature.

"2. That every subsequent occurrence of several days and nights of continuous high temperature causes the new attacks to be increased in number, and the former ones to be aggravated, through the month of July; the same, in a less degree, in August, and still less in September.

"3. That it is not simply the extreme of heat, but its duration, that determines the number and severity of the attacks, more especially of diarrhæa and cholera infantum.

"4. That the bowel affections under consideration prevail most in those cities and countries where there is a wide range of temperature between the winter and the summer; in other words, where these seasons present the greatest contrast." *

Dr. Davis further says † that "the facts tabulated in this and our previous report are sufficient to demonstrate clearly that the bowel affections of children which have been so long attributed, by the people and by many members of the profession, to *teething*, really originate from causes or circumstances of which a continuous or somewhat protracted high temperature constitutes an essential part."

There can be no doubt, at this late day, that there is a disorder, marked by peculiar features, which is especially liable to occur in very young children in hot weather, and which is just as distinct from ordinary infantile diarrhœa as cholera morbus in the adult differs, for example, from ordinary looseness of the bowels accompanying indigestion. Indeed, Meigs and Pepper‡ contend that cholera infantum is "the analogue of cholera morbus, or even of epidemic cholera in the adult," and with much force insist upon its distinction from ordinary simple and inflammatory diarrhœas. In enumerating its specific characters they do so very much in the words used by Dr. Aitken in describing epidemic cholera. Without multiplying references, we may again quote Bristowe, who, in speaking of *infantile diarrhœa* and *summer* (*English*) *cholera* of adults, says:§ "Although receiving different names, it would be difficult to draw any clear line of distinction between the morbid condi-

§ A Treatise on the Theory and Practice of Medicine, by John Syer Bristowe, M.D., London. Edited, with notes, by James Hutchinson, M.D. Philadelphia, 1876; page 703.

tions here associated." Dr. Smith* also notices this close resemblance of the symptoms to those of Asiatic cholera, "although quite distinct in its nature, and occurring independently of the epidemics of that disease." With sporadic cholera, however, the relationship is very close, and for all practical purposes cholera infantum may be considered as possessing all the clinical phenomena of cholera morbus.

The teaching of Meigs and Pepper may then be accepted without further discussion, that there is a true choleraic disease in infants as in adults, and that, pathologically, it is distinct from all the ordinary cases of diarrhœa or entero-colitis. What these specific characters are by which it may be recognized scarcely comes within the scope proposed for this present paper; for these the reader is referred to the exhaustive article on cholera infantum included in Meigs and Pepper's excellent treatise, or that of J. Lewis Smith, which has recently appeared in a fourth edition.

We are the more particular to establish its claims to be regarded as distinct from ordinary diarrhœa, from the fact that, in the words of a recent writer,† "in the discussion of this subject many of our physicians, and not a few of our writers, leave us more or less confused as to the nature and peculiar characteristics of the disease, there seeming to be a kind of tacit willingness to include all the intestinal troubles of the hot months under the head of cholera infantum."

Dunglison's Dictionary‡ may be held as in a measure responsible for this error, since, in its definition of cholera infantum, we find it regarded as synonymous with "summer complaint." We observe a further evidence of this in scanning the mortality lists of our large eastern cities. Taking Philadelphia, for instance, we find in the month of July, 1879, in addition to the (400) deaths from cholera infantum, that deaths of young children were reported from diarrhœa, marasmus, inanition, debility, teething, inflammation of the bowels, dysentery and cholera morbus. It is not improbable that some cases of true cholera infantum may be returned as marasmus, dysentery or diarrhœa, while there can be no doubt that many more of such cases are carelessly set down as cholera infantum. Indeed, an eminent authority already referred to says,§ "many physicians among us are still in the habit of designating the various intestinal disorders of children so frequent during the summer heats under the common title of cholera infantum. We believe, on the other hand, that a large majority of the deaths registered in our mortality returns under this name are the result, not of true choleraic disease, but of simple diarrhœa, or entero-colitis."

Having insisted upon the position of cholera infantum as a distinct disease, it may be provisionally defined as a choleraic disorder, which occurs in infants during periods of high temperature, and which is closely related to cholera morbus in the adult, if not identical with it.

In regard to its etiology, Eberle,* more than thirty years ago, pointed out its dependence upon an elevated temperature, and in discussing its causes, sagely observed that "There are, therefore, three causes whose concomitant influence is extensively concerned in the production of this variety of cholera, namely, high atmospheric heat, the contaminated air of large cities, and the irritation produced by dentition." To this statement it would appear that little has been, or indeed could be, added, although there is among recent writers a tendency to esteem less highly the last factor, and to disregard the erethism of the nervous system incident upon teething as a predisposing cause of cholera, although it will perhaps be acknowledged that it may lessen the power of resistance to the disease after its onset. There is, however, a general agreement to lay a greater stress upon, if not to attach exclusive importance to, meteorological phenomena in the causation of cholera infantum, and to pay less attention to the usual concomitants, such as teething, indigestion or diarrhœa, which may be either predisposing or accidental, according to circumstances. It is acknowledged that the observations of the relations existing between a sustained summer temperature and the appearance of the disease in certain large cities, both in America and Europe, are well founded; and that the conclusions of Mr. Turner, Profs. Davis and Miller, and systematic writers generally, are correct to this extent. The object of this paper will have been accomplished, if the writer succeeds in indicating, or rather suggesting, an answer to the query, "How does a continuous moderately elevated summer temperature, in certain localities, lead to the production of cholera infantum?

* Loc. cit.

† Prof. Miller. "A Contribution to the Etiology, Pathology and Therapeutics of Cholera Infantum," in the *American Journal of Obstetrics*, New York, April, 1879.

‡ Second edition, Philadelphia, 1868, p. 210.

§ Meigs and Pepper, loc. cit.

* A Treatise on the Practice of Medicine, by John Eberle, M.D., with notes and additions by Geo. McClellan, M.D.; 7th ed.; Phila., 1849.

In stating the above question the word "moderately" is advisedly used. In the same article in which Prof. Miller advances the view that a continued high temperature is "the *only* and *sufficient* cause of cholera infantum" (italics in the original), he defines the condition under which it appears as "a mean thermometer above 75°, with a small daily range." With the greatest deference to Prof. Miller's more extended experience, we would venture to differ *in toto* with him and other writers who adhere to the view that this degree of heat, *per se*, is sufficient to cause the disease; and we would here express the opinion that there are important physiological and pathological facts that we shall be obliged to overlook if we accept this doctrine. We oppose it the more firmly because this teaching, which is now becoming fashionable, leads to erroneous therapeutic deductions; we are permitted to infer that the case resembles one of heat-stroke or thermic fever (if, indeed, it is not to be considered as identical with it), and, therefore, is to be treated by the extraction of bodily heat (think of treating an adult with cholera morbus in this way!); it is also leading us in the wrong direction for prophylaxis, for it teaches that if the baby can be kept cool it is safe. The circular issued by the New York Board of Health says: "Wash your well children in *cold water* twice a day, and *oftener* in the hot season;" and Prof. Miller says: "If this one prescription were carried out, cholera infantum cases could be well nigh eliminated from the mortality reports." He looks forward to the time when the poor will be freely supplied with ice in summer, as an act of humanity, just as coal is given to them in winter. We think it will appear later that we should search deeper for the cause of this endemic disorder, for although heat is undoubtedly a link in the chain of causation, it is a remote one, and not the proximate one, as believed by many. We would not wish to be understood as in any manner condemning the use of graduated cool baths for children in cases of hyperpyrexia, nor of discouraging the adoption of all the means in our power of increasing the comfort, or rather of decreasing the discomfort, of our little patients, but it appears that some of our authors must have a different affection in their minds from what is properly designated cholera infantum, when they devote their attention chiefly to reducing the bodily temperature. Prof. Miller certainly must have meant something analogous to heat-stroke, or sunstroke, when, after recommending allowing the child small pieces of ice, and ice water, often repeated, he says, "As to the medicines to be used, as soon as cool surroundings are secured medicines will often be unnecessary, and so long as the temperature is not lowered they will generally be insufficient."* We would respectfully submit that whatever disease may be referred to here, it certainly is not cholera infantum, in which a fatal result may take place from collapse in five or six hours, and many die in less than forty-eight hours, with vomiting, thirst, rapid sinking, scanty or suppressed urine, watery stools, and wasting, in other words, with symptoms that cannot be distinguished from those of Asiatic cholera, the differential diagnosis being impossible during epidemics of the latter disease. (J. Lewis Smith.) Instances of *coup de soleil*, although rare, undoubtedly do occur among young children; but this condition is essentially and entirely distinct from cholera infantum,† although when fatal these cases are, without doubt, usually reported as instances of the latter affection. Sunstroke is caused by prolonged exposure to intense heat, generally to the direct rays of the sun, under circumstances that are adverse to free respiration and free perspiration; cholera infantum occurs under what, in comparison, may be regarded as not an immoderate degree of summer heat, and often where all ordinary precautions have been taken against its effects.

In brief, heat alone cannot be the sole cause of cholera infantum, for the following reasons:—

1. Physiology teaches that the various active phenomena occurring in the living organism are accompanied by the production of a large amount of sensible heat, which constantly escapes by radiation from the body, and which keeps the surface at a temperature corresponding with $98\frac{4}{10}°$ of Fahrenheit's scale. When the surrounding atmosphere approaches this degree of heat, radiation is checked, and discomfort is experienced, and bodily heat tends to increase; but Nature provides for this condition by bathing the surface in perspiration, which, in evaporating, cools the surface by appropriating large quantities of heat; at the same time there is a tendency on the part of the individual to avoid active exertion, and thus diminish heat production, so that workmen in foundries, glass-houses, and gas works may be habitually exposed to high temperatures, and where the air is dry they

* In another place in the same essay he states, "There are some striking resemblances between this disease and sunstroke, so much so as to suggest a pathological relationship."

† The differential diagnosis is given by Dr. Smith in the volume referred to, page 642.

readily support a temperature of 250° to 280°, and even, for a short time, of 350°, without much inconvenience.*

Now, there are many reasons why young children should bear a moderately high external temperature even better than adults, because their heat generating power is less. "It is to be carefully remembered that the development of man is slower than that of any other animal, and that his calorifying power is closely connected with his general bodily vigor; and though the infant becomes more independent of it as development advances, it is many years before the standard can be maintained without assistance throughout the ordinary vicissitudes of external temperature."† Milne Edwards and Villermé, in their researches into the causes of infant mortality in the foundling hospitals in France, determined that the excess was due to *cold* rather than to *heat*, and that the mortality is very much greater during the first three months of the year than during the summer, and that it varies in different localities, in proportion with the severity of the winter.

When we consider that a mean temperature of 75°, which is considered by some writers as the sole and efficient cause of cholera infantum, is by no means infrequently found to exist in children's nurseries during the winter, the extravagance of the statement becomes very evident. Indeed, the bodily temperature of the mother is considerably higher, but no one will contend that it is uncongenial for the infant or that it causes disease.

2. The geographical distribution of cholera infantum is opposed to the view of its causation solely by heat. Observers agree that it is most prevalent in a temperate climate, where the temperature rarely reaches 100° (in the shade). In many parts of the tropical zone, however, the thermometer rises every day, throughout a large part of the year, to 110°, and in British India and in Africa it is seen as high as 120° to 130°. In Siam the parturient woman is put close to a broiling fire, and kept there for thirty days after delivery.‡ The infant, of course, remains in the same room, and is nursed under this unusually high temperature. According to the heat theory all these children should die of cholera infantum, which is not the case. Another reason why heat is not the sole cause, is given by Eberle, and is abundantly confirmed by others—that the disease is much more prevalent in our large cities than in the country, where the temperature is equally high, and may be even higher.

3. Pathological considerations show that the choleraic disease of infants corresponds closely with cholera morbus in the adult, which we are not willing to believe is solely produced by heat, although usually occurring in hot weather. Finally, the external application of heat in animals * always produces symptoms of thermic fever or heat-stroke, which do not correspond in important particulars with those of cholera, either in the infant or the adult.

If the preceding propositions, will be accepted as demonstrated—(1) that cholera infantum is a disease pathologically distinct from ordinary diarrhœa; and (2) that although it occurs in our Middle and Eastern States during the periods of greatest temperature, it is not directly and solely due to summer heat—we may now proceed to consider what other meteorological conditions usually coexist with elevated temperature, that could influence the development of the disease. That this is the proper direction in which to search for the exciting cause of cholera infantum is evident from the facts that the disorder is not contagious, although endemic, and it is, beyond doubt, dependent upon meteorological states that are constantly associated with the prolonged heat of midsummer. Inasmuch as cholera infantum undeniably attacks children that do not drink impure water, and whose food is prepared with the greatest care, and who have due attention paid to bathing and proper clothing, we must look to the atmospheric surroundings for an explanation. It is acknowledged freely that a neglect of these hygienic precautions will produce sickness, and may possibly predispose the child to an attack of cholera infantum, but we contend that they cannot initiate the disease in the absence of the specific cause, as they exist in many places where cholera infantum is unknown.

The changes which occur in the atmosphere, especially of large cities, accompanying a prolonged high temperature, may be stated to be—

1st. An increase in humidity.

2d. Contamination by noxious exhalations of organic origin, crowd poison, etc.

3d. Changes of the air determined by conditions of the soil and movements of the groundwater.

* Chabert, the Fire-king, is said to have entered an oven heated to 600° Fahr.

† Carpenter's Physiology, American edition; Philadelphia, 1876; p. 547.

‡ Notes on Obstetric Practice in Siam, by Samuel R. House, M.D.; quoted from *Archives* of *Medicine*, by *Monthly Review of Medicine and Surgery*; Philadelphia, Aug., 1879.

* See Prof. H. C. Wood's Treatise on Thermic Fever; Philadelphia, 1876.

There is no doubt that all of these conditions may act as factors of disease, and systematic writers generally name impure air or poor ventilation as an active predisposing cause to cholera infantum.

In regard to the increase in humidity, this is recognized by sanitarians as an impurity, as it favors the suspension of organic particles, and the diffusion of carbonic acid. The dew-point rises in an increasing ratio with the temperature, and the air constantly contains from 50 to 75 per cent. of the quantity necessary for saturation. As the watery vapor is manifestly many times greater in summer than in winter, in favorable localities, it is a point in the propagation of summer complaints that should not be overlooked. This will be found to be particularly important, if the conclusions of Dr. T. J. Turner, U.S.N., shall be confirmed, in regard to moisture as an impurity in air. His positive statement is that when such vapor is in excess it has an absolutely fatal influence at a temperature of 90 to 100° Fahr.* If the truth of this shall be established by experimentation, it may be regarded hereafter as a leading, or, at least, an important predisposing, factor in the causation of cholera infantum.

Concerning the ordinary noxious exhalations from decaying organic refuse, and the contamination of the air by over-crowding, these evils are always present in our large cities. The thousands of cesspools, the miles of exposed gutters and untrapped sewers, the vegetable refuse that decays in the streets so readily in hot weather, are all active agents in the production of disease, and more especially in infants, since they are much more sensitive to bad hygienic surroundings than are adults. But since these causes are operative to an equal, and in many cases to a greater, degree when cholera infantum does not prevail, but the presence of the zymotic diseases, including diphtheria, testify to the insanitary conditions instead, it is evident that, while they deserve the prominence given to them in our classical treatises, as important adjuncts, they cannot be considered as being preëminently the cause of the disease under consideration.

* "Air and Moisture on Shipboard." Published by the Medical and Surgical Bureau of the Navy Department. This work I had not had the opportunity of examining, but only knew through an editorial on "Moisture as an Impurity in Air," in the New York *Medical Record*, for May 3d, 1879, in which Dr. Turner's conclusions are given; since writing this paper, however, I have, through the kindness of Prof. J. Aitken Meigs, had Dr. Turner's essay placed in my possession. It contains a number of practical suggestions for naval hygiene, and represents a large amount of original investigations.

Finally, we come to the consideration of the influence of changes in the atmosphere determined by conditions of the soil and movements of the ground-water. We confess that our convictions are in harmony with the view that it is in this direction that we are to look for the true cause of cholera infantum; and if it shall hereafter appear that there are good reasons for believing that the disorder is due to a specific cause, that its outbreak is associated with the development of microscopic or ultra-microscopic organisms, such as Pettenkofer* believes accompany cholera, both epidemic and sporadic, we shall consider it only as the final one of the series of clinical characters already referred to, unmistakably separating this disorder from ordinary ephemeral diarrhœa, and connecting it with cholera in the adult.

Largely owing to the careful researches of Pettenkofer, which have been repeated by other investigators, much greater attention, of late years, has been paid to the moisture in the soil, and the relations which it bears to certain epidemic diseases. The effluvia from the earth have been definitely connected with outbreaks of paroxysmal fevers, enteric (typhoid) fever, yellow fever, bilious remittent fever, cholera and dysentery.† The ground-water is defined by Pettenkofer as that condition in which all the interstices of the ground are filled with water, so that, except in so far as its particles are separated by solid portions of soil, there is a continuous sheet of water. Above this level the ground is moist, and contains air as well as water. This ground or subsoil water is at very different depths in different soils, from a few feet to several hundred, and is in constant movement, flowing toward the nearest river or the sea. In Munich, Pettenkofer reckons its rate at about 15 feet daily (Parkes). Its level is also constantly changing, from physical causes. When the ground-water is near the surface the soil is moist and cold, and favors the development of phthisis and paroxysmal fevers (it has been repeatedly observed that measures taken to dry the soil by deep drainage lessen the

* Neun ätiologische und prophylaktische Sätze, aus dem amtlichen Berichten über die Choleraepidemien in Ostindien und in den Vereinigten Staaten von Nordamerika, von Dr. Max von Pettenkofer (Separatabdrück aus der *Deutschen vierteljahr. für öffentliche Gesundheitspflege*, Band IX, Heft 2, Braünschweig, 1877. Also *Vierteljahrschrift für öffent. Gesundheitspflege*, Band II, page 181. Also his "Analysis of the Reasons of the Immunity of Lyons from Cholera," *Zeitsch. für Biologie*, Band IV, page 400; and numerous other essays.

† Parke's Manual of Hygiene, fifth edition; Philadelphia, 1878; p. 329.

prevalence of these diseases); catarrh and rheumatism also are found in such localities. To a greater degree, however, dampness of the soil exerts an evil effect, by aiding the development and evolution of organic emanations. These miasms "are at present known only by their effects; they may be mere chemical agencies, but more probably they are low forms of life, which grow and propagate in these conditions. At any rate, moisture appears to be an essential element in their production" (Parkes). There is a constant interchange, on the principle of diffusion of gases, going on between the ground and atmospheric air, which is favored by the rise and fall of the ground-water. This is a fruitful source of disease. Pettenkofer's observations led Buhl* to the discovery that in Munich there is a very close relation between the height of the ground-water and cases of typhoid fever; the outbreaks of typhoid fever occurred when the ground-water was lowest, and especially when, after having risen to an unusual height, it had rapidly fallen. This was subsequently confirmed by Pettenkofer, and by many others, the truth finding its most frequent application in large cities, where the ground-water becomes converted into an immense sewer, from the great number of cesspools. In addition to the conditions named, *i.e.* a rapid sinking of the ground-water after an unusual rise, and impurity of the soil from animal refuse, there is needed, according to Pettenkofer,† heat of soil and the presence of a specific germ.

A view almost identical with the preceding is held by the same distinguished authority in regard to cholera, which he considers due to a germ whose development is in like manner dependent upon the movements of the ground-water. He has published a number of essays in defense of this opinion, which is generally accepted in Germany, and the observations of Drs. Lewis and Cunningham in India demonstrated that the cholera in Calcutta, in 1873–74, occurred in accordance with Pettenkofer's views.

The field that has been opened by these researches in the "under world" is full of interest, and invites further exploration. Many of the apparent vagaries of zymotic disease may now find a simple explanation, and the study of future epidemics will throw still more light upon their origin and methods of propagation. It is especially upon the relations of cholera infantum to the movements of the ground-water and telluric exhalations, that the attention of American investigators of this subject should be directed. Cholera infantum occurs most frequently in cities, because its victims are there crowded in greatest number. It is not, however, confined to the cities, but is encountered in all its severity in suburban and country residences. An intelligent, experienced physician, practicing in one of the healthiest suburban localities near Philadelphia, told the writer last year that he then dreaded going to a case of cholera infantum, as he had seen quite a number, and they nearly all died, in spite of the greatest attention. We have since recalled the fact that at that period there had been a marked fall in the ground-water, and nearly all the wells in the neighborhood were dry. Coincident with this was an unusually hot term, which will long be remembered as the "hot wave" of 1878.

In the way of therapeutics and prophylaxis, the course is obvious. As in a cholera epidemic no apparently trifling diarrhœa should escape treatment, so during the existence of cholera infantum, no diarrhœa should be neglected; a child in the city with obstinate, watery diarrhœa, is to be regarded as threatened with cholera. The prophylaxis and treatment of cholera infantum might (having in view its epidemic character) be summed up in the simple recommendation to send the little sufferer, on the first symptoms of the disease, to the seashore, where it will often get well on mint water.*

When collapse is threatening, the warm mustard bath, with cool applications to the head, and a little burnt brandy internally, will revive the patient long enough to get him away from the infected locality.

In the hope of stimulating discussion, we would submit the following propositions, the last three of which it will be seen are far from being established at the present time:—

1. Cholera infantum is a disease of infants, *sui generis*, differing materially from ordinary summer diarrhœa, in its etiology, clinical history, and prognosis.

2. In all essential features, cholera infantum is the analogue of cholera morbus in the adult.

3. While its outbreaks follow the first continuous high temperature of summer, they are

not due directly to heat, nor is heat the sole and efficient cause.

4. Epidemics of cholera infantum, where circumstances are favorable for their development, follow a marked decline in the ground-water after an unusual rise (?).

5. Cholera infantum belongs to the zymotic group, and is due to a specific germ (similar to that of epidemic cholera)?

6. The specific agent producing cholera infantum is indigenous to certain localities, existing in the ground-air (?).

FAMILY TAINTS.

BY SAMUEL PETERS, M.D.,
Of Cohoes, New York.

The fact has often enough come to the observation of physicians, that some families of children have a low or weak vitality. Such families frequently, and I think as a rule, contain several members, even more than the average, so that we might term them large families; but they die, some with one disease some with another. Prominent among such fatal diseases we may name tubercular meningitis, scarlet fever, diphtheria, cholera infantum, etc., although almost any disease is likely to overpower the tender body and prove fatal. Thus we often see several little graves in a row, one after another having fallen a prey to some affection that others would have readily overcome.

What the peculiar constitutional character of such a family is, may in some cases be difficult to understand. We find, as a rule, the children are fair, intellectual, promising, even sometimes stout and rosy-cheeked, light skin and hair, yet possessing a certain *taint* which readily proves itself in unmistakable evidences of low grade of vitality, and for which, I believe, we have no name that will serve for all cases.

It may be remarked that the objective signs just named are not always present (Miller, Roberts). Some have dark skin and dull intellect.

I have observed that the parents may, and often do, appear to be quite healthy, with no indications, even to a physician's eye, that they must foster such a progeny. And what is more strange, they may not be in the line of any special hereditary disease, yet nearly every child seems to be doomed, sooner or later.

I have further observed that if one of the children was saved it was much more frequently the first—this to grow up perfect, or more or less feeble—the succeeding ones falling, one after another. Sometimes one, two or three survive, fortunately, but generally many more die than live; only a small part living to grow up.

It is certainly disheartening to the physician to observe such sad waste; families decimated, children dying in spite of all the known means that are at his command; and, indeed, he is often blamed for his ill success, when he has exercised a skill and judgment than which no better could have been found. Such sad mysteries, if the expression be allowed, sometimes confront us, and will continue to do so until we learn more of the great laws of reproduction.

However, some cases are clearly enough traced to their true cause; one or both parents exhibiting distinct evidences of loitering disease; or, though healthy themselves, yet falling directly in the line of hereditary disease. Or again, there may be a peculiar kind of exhaustion, which will be noticed hereafter. When such causes can be found our embarrassment is, of course, at an end. We say to the parents, "Your children are *tender;* they cannot endure as much as other children; they are like a vine growing in the cellar, easily snapped, and if you bear others, they also will be liable to fall as easily." It is, indeed, well that such a satisfactory explanation greatly mitigates their distress of mind.

But such families are occasionally found where no evident cause can be assigned. The parents are able to boast of uninterrupted health, and of entire freedom from hereditary disease; their ancestors have lived to a ripe old age, perhaps, and where the fault or failure exists cannot be told with any degree of satisfaction.

Among the family faults, or "taints," as they have been named, rather carelessly, perhaps, are scrofula, rheumatism, syphilis, general anæmia, and what we now term sexual exhaustion. I shall not take time to discuss these at any great length, only to make a few remarks on the first and last named.

While all these faults have more or less to do with the mortality among infants and children, it is undoubtedly the fact that scrofula is the most potent factor in the relation of cause, vitiating, as it does, the human system in such a manner that it is rendered incapable of withstanding disease to the extent that it otherwise would. In a word, scrofulous children are tender, delicate, frail; not in external appearance, perhaps, as already remarked, for they may be rosy-cheeked, even plump; "very healthy," as the parents will often say, but so in fact, as proved by the readiness with which they are swept away.

Now, all our observations, I believe, tend to confirm the opinion expressed by Rindfleisch (Ziemssen's Cyclopedia, vol. v.), which is based upon the researches of Virchow, regarding inflammatory exudations in scrofulous persons. I cannot do better than to quote from page 636 of the volume named: "Virchow first called attention to the predominant cellular character of the scrofulous exudation; to its hyperplastic nature, and to the low vitality of the cells which compose it. For my own part, I would add that fresh scrofulous exudations contain relatively *large* cells, with glistening protoplasm, and a nucleus in the act of segmenting, or containing a double nucleus. I have received the impression that the emigrated white blood globules, which in normal individuals pass from the blood vessels of the inflamed tract to some adjoining surface, or to the lymphatics or lymphatic glands, or become collected into abscesses, have a tendency, in scrofulous persons, to grow larger on their way through the connective tissue. They swell up by the intussusception of albuminous substances, and in this very swelling die and slowly degenerate. The consequences of this peculiar anomaly of vegetation are felt in all the inflammations of scrofulous persons; less in the superficial catarrhs of the skin and mucous membranes than in the deeper parenchymatous inflammations of the glands and viscera."

If this be true, that all inflammatory processes in the scrofulous are almost sure to pursue such a course, we may readily indicate to our own minds the cases in which lie the greatest danger; for whatever disease the scrofulous system encounters that has as a part and parcel any inflammatory process, of whatever surface or tissue, that disease will result, in a greater or less degree, in the complications and dangers just described. Hence, we have long ago learned to dread, in the scrofulous, the diseases to which children are especially liable which have an inflammatory or even a hyperæmic character. The same explanation, I have no doubt, can be given of the serious results which sometimes follow vaccinations in these subjects, even with the purest virus. No amount of care can always avert such unpleasant consequences. All are aware of the great difference in the results which follow ordinary injuries, as, for instance, of the joints, or other parts, the difference being determined by this deep-rooted all-pervading constitutional taint.

But another cause may undoubtedly be assigned for the low vitality in children of certain families; a cause which is now and then simply mentioned, but not really dwelt upon and distinctively urged, yet I believe a very prolific one in inducing the bodily condition under consideration. I refer to sexual exhaustion, commonly induced, as is well known, by the frequency or rapidity of conceptions; also by the ruinous practice of imperfect or incomplete coitus, and perhaps by repeated abortions. I cannot but think that sexual exhaustion as a cause of low vitality is not receiving its due share of attention; that the public is not properly enlightened, through the profession; that we are perhaps criminally negligent in failing to discharge so vitally important a duty, while it is carrying off, probably, as many as all the other causes we have named, except, possibly, scrofula, and even this, with all its evils, may frequently be engendered by it.

Sufficient, however, has been said on these points, as my principal object in this paper was to speak more especially upon the physician's part in the management of such families, by moral, hygienic, and medicinal treatment. That we may do much to fortify such constitutions against what may, and, indeed, must be, encountered, is admitted by all. Not that we can in all cases entirely eradicate the cachexia, but that we may so far neutralize its influence or power that the system will not so easily succumb to the influence of disease. In other words, that we may raise the grade of vitality, and perhaps, even, in some cases, place it on a level with the strongest.

The hygienic management of such families is all important, and pretty well understood, even by the laity, so that generally, as far as possible, it is carried out, and with great benefit too. But for this fact thousands would die in their early years who are now, in these days of better intelligence, saved. We are continually urging upon parents, and very properly, the importance of all hygienic points in the management of their families, particularly proper exercise, good air, and suitable food and clothing. The importance of proper food none will question, and it may be affirmed that the mother's milk, if healthy, and cow's milk, where it can be obtained pure, is all that is required. In regard to the various "foods" that are advertised so extensively, I have little experience, having, first, a strong prejudice against all such preparations for infants and children, because I believe nature to be the best chemist in providing her own nutriment, and secondly, because milk has invariably proved itself all sufficient.

Proper clothing is of equal importance, but it is readily understood that all these requisites

cannot be carried out by a large proportion of the families, on account of pecuniary inability. Good air, good food, and good clothing are not the gifts of poverty. Fortunately, however, milk is, in most places, abundant and cheap, and a portion of it each day, with even coarse food, will build up many a poor body.

Aside from such judicious management, I know of none that offers to us more promise of success than a persevering course of cod-liver oil. After much careful observation of its effects I can confidently affirm that cases such as we have been considering form a large class, in which the benefits of this *great remedy* are too little understood. Not that its value is underrated in the various and actual *diseases* that are commonly called scrofulous; not that it is neglected when disease has fairly invaded the system; for these all acknowledge its potency for good; but as a *modifier* of the whole organization, *before* disease has invaded it, even while it is yet unsuspected, and during the early months of life, then it is that this remedy is most valuable. As Prof. Geo. B. Wood says of mercury, so I say of this remedy, it "revolutionizes" the whole body, builds up every cell, reorganizes, so to speak, the vital forces, and makes the child apparently another being. Therefore, as a preventive, as a fortifier, I would recall the attention of the profession to it, believing, as I do, that it is too much neglected.

From happy observation, in very many instances, I have found it to so enhance the powers of endurance that disease would not take on so readily fatal forms, or meet with so many complications. With this understanding of the relation of cod-liver oil to such constitutions, the natural conclusion is that the sooner its beneficial effects can be realized, the earlier it can be given, the more hopeful we may be of success.

In order to illustrate properly my experience in the matter, I will cite an instance, one of a number that could be given. It is a family by the name of Butler; the father and mother apparently healthy; had a child, the first, that with some evidences of a delicate constitution, has grown to be a boy of nine years. The second child, at eleven months of age, died of marasmus. The third began to decline at four months, after being urged to administer cod-liver oil. This the mother neglected, or rather refused to do. A few months after it was attacked with dysenteric spmptoms and died. After the birth of the fourth child the parents were urged still more strongly to administer the remedy early. It was neglected again, and this one died at the age of eleven months. She then promised if another should be born she would administer the remedy. She did so for several months, commencing soon after its birth, and it has now passed three summers, and is healthy. She has now the sixth, thirteen months old, to which was also given the oil faithfully, and which is as promising as the last.

I think the remedy should be administered early; if possible, long before the first summer, and continued diligently, in such doses as the little stomach will bear. I have not generally discontinued its use upon the occurrence of an ordinary diarrhœa or dysentery, for, with Ringer, I find it often seems to benefit such cases, especially the latter. It is needless to say it should be continued several months, if possible.

To omit the discussion of the operation of cod-liver oil is excusable, as our present knowledge has not enabled us to come to any satisfactory conclusion in other diseases in which its beneficial effects are acknowledged. Certainly, it is a compound of many and valuable constituents. According to De Jongh (U. S. Dispensatory), these consist of iodine, bromine, chlorine, phosphoric and sulphuric acids, phosphorus, lime, magnesia, soda, iron, glycerine, various biliary principles, a peculiar substance, called gaduin, several other peculiar substances not named, etc. The thousands of gallons that are consumed every year is certainly good proof of the high esteem in which it is held by the profession as well as the public, even though its operation is somewhat mysterious.

I am aware that such a general recommendation of this remedy nearly approaches empyricism. And at this point I wish to call attention to the remarks of Niemeyer, that cod-liver oil is used in scrofulous diseases too indiscriminately; that it is needless to administer it to any but those who are *lean*, with little or no adipose tissue, etc. This is undoubtedly true in reference to tubercular affections, but I must dissent from it in the cases I have mentioned, especially in infants and young children who have *not* yet reached the tubercular or disease stage.

Many other points bearing upon this subject might be discussed, but I shall take time to offer a very few remarks upon only one, and that is, weaning from the mother. Much might here be said in quoting the opinion of others, but I must be content in stating some practical points which have impressed themselves after many years of observation.

It is evident that a healthy mother, with

healthy milk, should nurse her own child; on the other hand, if unhealthy, she should not. But can we always determine accurately this point? It is a fact that a healthy, or, certainly, an apparently healthy mother, may secrete unhealthy milk. Such cases have come under my own observation, and doubtless many others have noticed the same thing.

Dr. Jacobi, of New York City, has recently (*American Journal of Obstetrics*, volume XII, page 541) given some indispensable instructions, which all must appreciate, and which very clearly intimate an endorsement of the points in infant therapeutics, etc., upon which I am speaking.

Bedford, in his "Diseases of Women and Children," gives excellent advice on lactation and weaning, which it would do well for all to consider. He refers to a child suffering with a persistent diarrhœa which apparently had baffled ordinary treatment. He examined the mother's milk and found it to contain colostrum, which should be found in the breasts for only the first few days after delivery, as is well known. He weaned the child and the cure followed spontaneously.

Similar facts I have known in regard to cow's milk. One family had two cows; from one the child was fed and did well. The other cow's milk acted speedily and always as a cathartic, and the mother told me that whenever she desired to administer a cathartic to her child she gave it the milk from this second cow. Both cows were equally healthy. Another family had a cow the milk from which always produced an eruption on the child's skin. After several trials and experiments, the milk was necessarily abandoned. Why may not human milk sometimes present the same anomalies?

The truth is, we may estimate approximately, never with precision; therefore, when a child fails to do well with good medical advice, it is certainly good practice to wean it from the mother, unless the time approaches too near the hot months, and either find a wet nurse, or, better still, generally, raise it on cow's milk. Indeed, I generally feel a sense of relief when any circumstance induces parents to rear their scrofulous or tainted children on cow's milk. This I am willing to repeat with emphasis, having long ago formed the belief that mothers in these modern days are too commonly unfit to nurse their children.

It must be acknowledged that one very serious obstacle exists to the general adoption of this advice. It is the changed, unnatural condition of cow's milk as found in the larger cities; a change that appears to be decided and unmistakable. While this fact is sufficiently known and acknowledged, it is undoubtedly true that physicians in such cities scarcely appreciate it in its full length and breadth.

Milk in the city and country is, indeed, two different fluids; different in nearly all points. The fat is more irritating, because more indigestible; the casein forms in the stomach in larger and denser masses; even the salts are not in such perfect solution, besides being chemically changed by the external forces to which city milk is necessarily subjected. It is often rendered unfit for any stomach, especially that of the tender infant.

In the country the milk is at once and carefully carried to a cool, dark cellar, strained, placed in pans, and left undisturbed, and away from light and heat. It is scarcely changed, chemically or physically, from one milking to the next. It is simply sweet, pure, fresh, untouched, perfect. In the city it is in every respect exactly the reverse, particularly in warm weather; the long agitation in its transportation, the heat, the light, and too often the adulteration with chalk, magnesia, water, or whatever the peculiar "receipt" of different dealers directs, rendering it a pabulum entirely changed from the condition in which nature left it. Hence we might well say: In the city raise an infant on breast milk, in the country on either, all things being equal.

It is easy to perceive why such a discrepancy exists in instructions of writers on the management of infants; one having never known or tasted of pure country milk, the other entirely ignorant of the quality of milk as vended in the cities.

It is equally easy to understand, also, why a removal from the city to the country will often rapidly benefit the sick child, the food, especially the milk, more than the air, in my humble opinion, conducing to this happy result. In the latter place the question of infant dietetics becomes much more easy, and, therefore, the therapeutical one proportionately simplified. Even the milk obtained from a cow kept in the city is often injured while in the udder, by driving her a long distance from pasture. She is almost sure to be fed more or less on slop, which is so easily obtained from neighboring dwellings, besides being kept at night in small, smothering stables.

All this, however, does not invalidate the fact, as I deem it, that pure, fresh cow's milk is only second, if not fully equal, to the material fur-

nished by the mother; diluted with pure water for the first four months, afterward given in its full strength.

What, then, it is asked, is the best thing that can be done with infants in the large cities, who are obliged to remain? The answer may readily suggest itself, if we fully comprehend the causes which produce deterioration of milk. Imitate, as far as possible, the treatment it receives in the country, and particularly among small dairymen, where only it is to be found in its greatest perfection. Avoid agitation, admixture, heat and light, and certainly all this can be done to a considerable extent. First, the supply for the family should be taken fresh from the cow, at least twice a day, carried by hand, and as short a distance as possible; secondly, this should be done in an absolutely cool and cooling receptacle, and third, it should be kept carefully in a cool cellar, or in a common refrigerator, from which it is to be taken only in small quantities, as required, warmed and given to the child. I am satisfied, from personal observation, that such precautions will repay the little extra trouble involved.

The conclusions which may be drawn from clinical experience, and to which I invite attention, are—

1. That "taints" exist much more frequently in children of families than in the parents.

2. That such taints produce a low grade of vitality.

3. That among these taints or defects scrofula and sexual exhaustion are the most common.

4. That external appearances and the family history do not always point to these constitutional defects.

5. That the unnatural and ready yielding of the body to disease is often the first evidence we have of the existence of taint.

6. That disease in such a body is not what the same disease is in one that is free from such fault.

7. That cod-liver oil is often capable of neutralizing such faults, or in other words, of revolutionizing the vital forces.

8. That to accomplish this the remedy is to be given early in life, and *before evident disease commences.*

Editorial Department.

Periscope.

Vasomotor and Trophic Neuroses.

At the Medical Society of London, recently, Dr. Dowse commenced a paper on this subject by stating that under the head of nervous disorders was embraced not only our objective material and volitional parts, but also the co-relation of these with subjective as well as mental morbid processes. The nervous system embraced a chain of phenomena by which were linked together all parts of our conscious and unconscious being; and it was impossible, even at the present day, to say how far and by what means these were intimately associated. Eulenburg and Guttman, in their essay, stated that certain well known investigations had placed it beyond doubt that the vasomotor centre for most parts (including the head) was in the medulla oblongata; and not only had Budge's former experiments proved the influence of the pedunculus cerebri on the vessels of the opposite half of the body, but their own investigations showed that certain defined localizable vasomotor districts existed in the surface of the brain in dogs, in the upper part of the cortical substance; and the experiments of Goltz upon the sciatic nerve and lumbar part of the spinal marrow of dogs had proved that there were two kinds of fibres governing the movements of vessels, the one dilating and the other contracting them. It was by the due correlative action of these nerves that the tone of the vessels and nutrition of parts were maintained. Trophic nerves had, up to the present time, not been made evident by dissection; yet from analogy, it was quite rational to infer that they had an independent existence. It had been shown, by M. Claude Bernard and others, that the branches of the sympathetic nerves might be divided without producing any alteration in the nutrition of parts, although the resulting congestion might be intense and prolonged; and that it followed, as a rule, that the congestions arising from paralysis of the vasomotor nerves and derangements in the nutrition of parts were, as far as clinical teaching and experimental physiology showed, quite independent of each other. M. Brown-Séquard had shown that paralysis of a vasomotor nerve might be carried so far that not even a drop of blood flowed on pricking the skin; that the vitality decreased and the parts became pallid and cold, but no changes in nutrition occurred. It was not uncommon to find cases, notably among hysterical patients, where there was a very intense and persistent check to the circulation, yet troubles of nutrition did not arise under these circumstances, so that we were compelled to fall back upon what he admitted was in a measure theoretical: "That there was a set of nerves intimately associated with

compound cerebro-spinal nerves which had an especial function in regulating and controlling nutritive processes." There was no better established fact in the whole range of neuro-pathology than in those disorders of nutrition of distant parts of the body which resulted from destruction to brain tissue by vascular changes; and these took a direct course in conformity with the histological direction of the nerves implicated; and deaths arising from this cause were often more frequent than from the primary seat of disease in the brain and spinal cord. By way of examples, he referred to bed sores and to the rapid destruction of the mucous surface of the bladder and urinary tract. He pointed out that consecutive lesions of nutrition to central brain disease sometimes deceived the physician, who mistook them for the disease itself. Dr. Dowse continued his paper by drawing attention to the part played by the vasomotor and trophic nerves in hemicrania, angina pectoris, facial hemiatrophy, muscular atrophy, and pseudo-muscular hypertrophy.

The Hyposulphites in Smallpox.

Dr. Hardaway writes, in the St. Louis *Courier of Medicine*—

When Inspector of Smallpox in this city, during the epidemic, some years ago, I had many hundreds of cases of variola under my observation, with the opportunity of testing various plans of treatment in that disease. As the result of my experience, I came to the conclusion that the hyposulphite of sodium was an invaluable remedy for smallpox. If Polli's theory of the action of these drugs is at all tenable, then surely they are indicated in variola. Owing to the influence of previous vaccinations in modifying smallpox it is particularly difficult to arrive at any very exact conclusions as to the effect of medication; but having treated all types of the disease, and many unvaccinated children, with the hyposulphite, I am prepared to state that my results were highly encouraging. One thing that I frequently noticed in using the hyposulphite, was the prevention or modification of the pitting—a result that, with my present experience, I would be led to expect.

Iodine in Malarial Fever.

On this subject Dr. Wm. Anderson has an article in the *Proceedings* of the Kings County Medical Society, from which we make the following extract. He had used it largely in the Brooklyn Dispensary:—

The time required to effect a cure naturally varied. In a large number there was no paroxysm after the first dose; frequently it took two or three days before any mitigation was observed. While it was seldom necessary to repeat the usual two or three ounce mixture, it occasionally happened that the fever returned when the medicine was omitted for a few days, but was again promptly subdued on a renewal of the iodine. That there is such a thing as a permanent cure for this subtle and Protean disease, even with iodine, I very much doubt; and no educated physician would promise it under any form of treatment. As to the question of relapse, I believe there is less chance of a return than after treatment by quinia. I have had several patients return the following year for their iodine prescription, which they remembered as having given them prompt relief; but this experience is doubtless common to all forms of treatment.

Iodine is so seldom prescribed for internal use in any form of disease, and it is so customary to consider it as an external agent, that most physicians look with suspicion on the idea of substituting it for quinia. Very many think the stomach would not tolerate it. This idea, however, is merely the result of inexperience. The extent to which Lugol carried the exhibition of iodine ought to be sufficient proof of its safety, if not of its usefulness. In the dose recommended, and properly diluted, it is quite palatable, and can be borne by almost every one. I have had but one patient who could not retain it, but neither could she retain a solution of quinia, and was only relieved when I prescribed quinia in capsules. Children take it readily—that is, where they will take anything readily. I have given it to children of all ages, and have not had a fraction of the trouble I formerly experienced with quinia.

When I commenced this line of treatment I used the simple tincture of iodine in syrup and water; but while this acted well therapeutically, it was found advisable to add iodide of potassium to the mixture, to prevent precipitation of the iodine. For adults I usually prescribed twelve to fifteen minims of the compound tincture, freely diluted, to be taken three times a day, after food, and regardless of pyrexia. From five to ten minims usually sufficed for children. Larger doses were frequently employed in severe cases, without producing any unpleasant results. My usual prescription in private practice is as follows:—

℞. Tinc. iodinii comp., ℥ vj
Syr. acaciæ, ℥ xviij. M.

Sig.—Teaspoonful in a wineglassful of water three times a day, after food.

The compound solution of iodine would answer equally well, and would come cheaper for dispensaries, or those physicians who give out their own medicine. The iodine may be combined with any other drug indicated, and I now frequently use elixir of eucalyptus as a vehicle; but I was careful for a long time to use no combinations that might complicate the experiment.

Prevention of Mammary Abscess.

The following not new but useful plan is recommended by Dr. Shepherd, in the *Canada Medical and Surgical Journal*, August:—

When the gland becomes indurated, painful, and has a glistening red look (symptoms, in fact, of approaching suppuration), take a large piece of ordinary sticking plaster and cut it a circular shape (a larger or smaller disc, according to the size of the affected breast); make a hole in the centre large enough to allow the nipple and half the areola to be seen, and apply this piece of plaster (after heating it) so that it will cover the whole breast, and that the nipple will protrude through the aperture in the centre. To make the

plaster fit more accurately, its circumference should be deeply nicked at distances of about an inch. The plaster should be left on till the breast softens, or the plaster ceases to exercise even pressure. This simple method, in the half dozen cases I have seen it used, has acted magically, the breast softening and the pain disappearing in the course of twenty-four hours. In one case a woman who had suffered on several previous occasions from broken breasts came to the out-door department of the General Hospital with all the symptoms of fast approaching suppuration in her right breast; in fact, I considered that within twenty-four hours I should be obliged to use the knife. However, I said to the students that if there was anything in the plaster remedy this would be a good case in which to try it. I applied the plaster in the way described above. Two days after the woman returned and said, with a pleased smile, that it was the only remedy she had ever tried that had done her any good; that on previous occasions every remedy had failed to prevent her having a "broken breast." On examining the breast, I found it quite soft, painless, and with only one small lump of induration on the upper part, which disappeared in the course of a couple of days.

When to Induce Premature Labor in Puerperal Eclampsia.

On this question Dr. W. W. Potter writes, in the *American Journal of Obstetrics*—

The proper time to induce premature labor in puerperal eclampsia becomes at once an interesting and important question.

Will it be wise to resort to the measure early; or shall it be postponed until other means have been tried and found insufficient? While these are questions, speaking generally, which must be determined from the observation and study of each individual case, yet I opine there is more frequent occasion to regret too great delay in the employment of this method, than that it has been invoked too early.

Observation and experience, those final arbiters of all questions medical, have settled some general principles pertaining to this whole subject, from which I formulate the following:—

1. It is wiser to err on the side of safety to the mother, and induce labor too soon, than to temporize until it is too late. When the uterine body has attained sufficient size to interfere materially with the return blood current, the indication is most clear. This will especially be the case if there is deep coma in the interval of the fits, indicating great activity of the blood poison. Here the urgency is pressing, and prompt action may save life. In hesitation there may be disaster.

2. The amount of albumen in the urine is not a sure indication of the extent of the blood poison, since in many of the severer cases there are but slight traces of albumen, and in others it is wanting altogether; while, on the other hand, albuminuria is frequently found in pregnant woman who do not subsequently have convulsions.

3. From this it may be inferred that the practice of inducing labor when there is albuminuria *without* convulsions is a questionable one; its employment as a necessity, at least, being limited to a small minority of cases.

Memoranda for the Disinfection of Yellow Fever.

The following rules have been published by the National Board of Health:—

1. It is prudent to assume that the essential cause of yellow fever is what may, for conciseness, be called a "germ," that is, something which is capable of growth and propagation outside the living human body; that this germ flourishes especially in decaying organic matter or filth, and that disinfection must have reference both to the germ and to that in or on which it flourishes.

2. Disinfection, when used in a place not infected, for the purpose of rendering filth, or foul soils, waters, etc., incapable of propagating disease germs, is a poor substitute for cleanliness, and is mainly useful to make the process of cleansing odorless and harmless. The best disinfectants for this purpose are sulphate of iron, carbolic acid, fresh quick-lime, fresh charcoal powder, chloride of zinc, chloride of aluminium, and permanganate of potash.

3. The two great difficulties in destroying the vitality of the germ of yellow fever are, first, to bring the disinfecting agent into actual contact with the germ; and, second, to avoid injuring or destroying other things which should be preserved.

4. *When the germ of yellow fever is dry, or partially dried, no gaseous disinfectant can be relied on to destroy it.* It must either be moistened or subjected to a dry heat of not less than 250° F., to obtain security.

5. In disinfecting or destroying infected clothing, bedding, or movable articles, *move them as little as possible while dry.* Before disturbing them have them thoroughly moistened, either with a chemical disinfecting solution or with boiling water, in order to prevent the diffusion of dried germs in the air in the form of dust.

6. The best method of disinfecting rooms, buildings, ships, etc., is still doubtful, owing to the difficulty of destroying the vitality of dried germs.

The Board proposes to have this subject carefully investigated, and in the meantime advises thorough scrubbing and moist cleansing, to be followed by the fumes of burning sulphur, at the rate of 18 ounces per 1,000 cubic feet of space to be disinfected.

The sulphur should be broken in small pieces, burned over vessels containing water or sand, which vessels should be distributed in the closed space to be disinfected at the rate of one to each 100 square feet of area of floor,

7. No patented compound known to the Board is superior, as a disinfectant, to the agents above mentioned, and none is so cheap. Some of these patent disinfectants are good deodorants, but *the removal of an unpleasant odor is no proof that true disinfection has been accomplished.*

8. In districts where yellow fever prevailed last year the following precautionary measures should be taken:

(*a*) Textile fabrics of every description which were exposed to yellow fever infection during the year 1878 and which have remained packed or

boxed in a closed space since such exposure, should not be opened or unrolled, but should either be burned or placed in boiling water for half an hour or more, or in suitable heated ovens, or disinfected, according to the nature and value of the individual article or articles.

(*b*) Every house or room in which cases of yellow fever occurred in the year 1878, and since that time have remained unoccupied, should not be opened for occupation until they have been thoroughly cleansed and disinfected, by persons acclimated to yellow fever.

(*c*) Every privy, vault, under-ground water-cistern, dry well, or closed cellar, connected with a house in which yellow fever existed last year, and which may not have been opened since that date, should not be reopened, but if possible should be covered with several feet of earth.

(*d*) Every suspicious case of sickness should be at once isolated, and every possible precaution taken to prevent infection, by providing attendants who have had the disease, and thorough disinfection of all discharges from the sick. If the disease prove to be yellow fever, all articles of clothing and bedding used about the sick should be burned, the house should be vacated, and every room tightly closed and fumigated with burning sulphur.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——"Volume I, No. 1," appears on half a dozen periodicals which reached us last week. A few words will be due each of these new births. "The American Journal of Electrology and Neurology," edited by John Butler, M.D., and published by Boricke & Tafel, New York, is to be a quarterly, supported by homœopathic writers on this specialty. The "Journal of the Eclectic and Liberal Medical Association of Eastern Indiana" is edited by N. G. Smith, M.D., of Lewisville, Ind. Its scope is obvious from the title. Enough of it. The "Home Medical Journal" comes from Boston, Mass. It announces that it is "devoted to the interests of health and hygiene in American households." These interests will not be furthered by the numerous quack advertisements it contains. "The New Era; Organ of the Law and Order Temperance Movement in Ohio," Columbus, Ohio; a rabid prohibition sheet. "The Cosmopolite," of Sioux City, Iowa, which looks as if it was started in the land selling interests.

——Several reprints in the department of ophthalmology have been received from Dr. M. Landesberg, of this city. They show him to be an acute observer and faithful student. In one of his latest papers, "on the therapeutic uses of Eserine in glaucoma," he gives what is likely to be a needed warning, which we quote in his own words:—

"If I draw the *final conclusion* from my observations, I must regard eserine to be not only an unreliable, and, in the most cases, worthless remedy in glaucoma, but also a very dangerous one, which, by its primary results, may lull the patient as well as the attending physician into a delusive security, endangering thus the favorable chances of another more efficacious therapeutic action. Especially insidious is eserine in the hand of the patient. The latter, convinced by the primary results of the high value of the remedy, will resort to it in all the following paroxysms, without consulting the physician, and will only desist from his experiments when a larger part of the sight has been irrevocably lost."

——The annual report of the State Lunatic Asylum, Utica, N. Y., contains the usual statistics, and also an interesting pathological report, giving the post-mortems of a number of cases. The superintendent makes the following important observation on the results of these autopsies:—

"In regard to the pathological affections of the ganglionic elements of the nervous centres, it seems that the so-called pigmentary degeneration resulting from the absorption and deposition of material in the protoplasm of the ganglion cells, furnished by the decomposition of emigrated red blood corpuscles, is of far more import than has hitherto been admitted. Especially in the brain of paretics it can be demonstrated that this pathological process may lead to a complete destruction of the ganglion cells, to a transformation into granular, dark-brown colored masses, with disintegrated prolongations resembling the former cell body only in the raw outlines."

——An able and timely monograph has been published by Delahaye & Co., Paris, entitled "La Trepanation Guidée par les Localisations Cérébrales. Par le Docteur J. Lucas-Championnière, Chirurgien des Hôpitaux, Rédacteur en Chef du *Journal de Médecine et Chirurgie pratiques*, membre de la Société de Chirurgie. 1 vol. in-8 de 180 pages; price 3.50 fcs." The author studies very successfully the records of trephining, to show the observed effect of the operation on nervous lesions coincident with the wound. He believes functional localization opens a new field for the operation. He goes so far as to formulate the rule, that given certain motor troubles consecutive to lesions of the skull, it is possible by their study to determine sufficiently precisely the cerebral lobe implicated to guide the hand of the surgeon in operative measures on the skull by trepanation. Certainly, if anything near this can be achieved, the advance is great. The work will be studied with interest by surgeons.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Half-Yearly Compendium of Med. Science,	**2.50**
Reporter and Compendium, - - -	**7.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**8.25**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE FACTOR OF TEMPERATURE IN CLIMATE.

The most prominently important feature in the geography of a health resort is its temperature. It is astonishing how little is understood by even professional writers on this subject, and how rarely are we furnished with information which fully covers all that the reader must know in order to form a correct opinion as to the sensations of heat and cold he is likely to experience in a given locality. These sensations are far from being indicated by an ordinary thermometrical record; and we shall proceed to point out exhaustively what elements are indispensable to a correct understanding of temperature as it affects sensation. We preface our remarks by saying that in the numerous articles and books we have examined on this topic we have not found a single one which fulfills the conditions necessary to accuracy.

First, it is obvious to all that a yearly, seasonal or monthly average of thermometrical readings is of scarcely any value at all in this connection. Even a table of daily averages is no better. For example, a daily average of about 70° is found in certain months at Callao, Peru, and also in the desert of Gobi; but there is not the least similarity in the sensations of heat and cold experienced in the two localities; for, whereas in Callao the thermometer rarely varies 10° in the twenty-four hours, in the desert of Gobi it is not uncommon to have at midday a temperatnre of 90 to 95° in the shade, and at night to see the mercury below the freezing point. Hence, the *range* of the thermometrical readings is much more important than the *average*. DOVE recommended that, for practical purposes, periods of *five days* should be selected as sufficiently short and convenient of mathematical handling, and in these periods the maximum, minimum and average be shown. To give the monthly range he very properly condemned as valueless for purposes of comparison of sensation.

The *solar power* is another very important element in a climate. We have frequently heard patients speak of it, but it rarely appears in meteorological records. Yet its effect on personal comfort is great. Along the Riviera the out-door air in winter is very pleasant in the sun, but in the shade is singularly chilly and penetrating. In the Lake Superior region, in summer, the rays of the sun are frequently unpleasantly hot, while the shade is disagreeably cold. Localities differ widely in this respect. At Muscat, in Arabia, the difference between the temperature in the shade and in the sun has been noted at times at over 90° Fahr.! Such differences as these greatly diminish the claims of a spot to being a pleasant one for sensitive subjects.

Even where the range is low, and the solar power moderate, very wide differences in sensation are experienced, owing to the amount of *moisture* in the atmosphere. The comparison of the wet and dry bulbs is indispensable to an understanding of a climate. All know that a dry cold or heat affects sensation far less than when the air is damp. We have seen a room in a Turkish bath heated to 235°—more than 20° hotter than boiling water—yet bathers remained in it for several minutes with impunity, as the air was

thoroughly dried. The least moisture would have scalded them to death. On the other hand, at Davos, in Switzerland, in the dry Alpine air, consumptives and other delicate patients will sit out of doors without overcoats, when the thermometer is below the freezing point, and neither suffer from cold nor experience ill results. Moisture promptly exalts the sensations. An experienced traveler told us the most oppressive heat he had ever experienced was in the moist season on the Caribbean Sea, when the thermometer was not above 80° or 82°, but the air was saturated with moisture. What in Calcutta is known as "sunstroke weather" is when the sky is clouded and the atmosphere foggy, although the sun is obscured. A damp cold is well known to be of the "chilling" kind.

Another factor that influences our sensations is the motion of the air, the *wind*. Bayard Taylor, who experienced a cold of 50° below zero in Lapland, says it is bearable so long as there is no wind, but with a strong gale it is almost certainly fatal. The unpleasant sensation of coldness is aggravated by winds up to a temperature of about 70°; while over that they act agreeably, by reducing the sensation of excessive heat. There are, however, some exceptions to the latter statement. The Sarmattan and other winds from the deserts of Sahara and Arabia are, for some not very clear reason, far more oppressive than a still air of the same temperature, and they retain this character, no matter whether they blow directly from the desert, as at Cairo or Muscat, or whether they have passed over hundreds of leagues of sea, as when they reach Genoa or the Madeira Islands. A similar land wind prevails at times at Buenos Ayres, which has a peculiarly exciting and irritating effect on the nervous system. When it blows the best natured man grows crusty, and the virtues of patience and affability are at a high premium.

The *atmospheric pressure* also influences the sensations of heat and cold. As a rule, the greater the pressure, the more sensitive are the nerves to impressions of temperature. Residents on high plateaux are never sunstruck and support cold well. The demands made by the respiratory and circulatory system on account of the rarefied air explain this to a degree; and the relation of pressure to moisture also comes in for a share.

Finally, the *earth temperature* must be considered. All know that at a distance, which varies with the character of the soil, below the surface of the earth, a point is reached where a thermometer will constantly register the mean temperature of the locality. Approximately, the greater the absorption of heat by the soil, the deeper will this point be; and, of course, the deeper the heat penetrates the soil, the slower will radiation be, and consequently the more gradual the change from the diurnal to the nocturnal extremes, and hence, the more safe and agreeable will be out-door life and residence on ground floors.

All the above data must be furnished before a reader can form a correct opinion of a health resort, with reference to this single feature of its effects on sensations of heat and cold. Yet, we repeat, we have not found one description in which these data are supplied. We had it in mind to take up a few of the late circulars and books on health resorts, and illustrate how absurdly deficient they are, but we think better of it, and will let the reader do so for himself. One remark, however, we may add, and that is, that so long as medical writers are contented to give such lame and inadequate attention to these climatic considerations the important remedial resource of a change of climate will continue in the same foggy, vague and unsatisfactory condition that it now is, instead of being the most potent for good in many diseases, which it could be made.

Notes and Comments.

Therapeutical Notes.

BARIUM CHLORIDE IN ANEURISM.

This substance, in doses of gr. $\frac{1}{5}$–$\frac{2}{5}$, three times a day, has been successfully tried in aneurism by Dr. F. Flint (*Practitioner*, July, 1879). He says of it:—

"In my opinion preference should be given to the chloride of barium in fusiform aneurisms, which have hitherto not been very amenable to

treatment; also in the aneurisms of advanced age; and it might also be tried in any case in which iodide of potassium is inadmissible, or does not promise to be useful."

EUCALYPTUS IN NEPHRITIS.

In albuminuria and post-scarlatinal nephritis, Dr. Wm. Anderson, of Brooklyn, has used, with good results, the elixir and fluid extract of eucalyptus (*Proceedings of Kings' Co. Medical Society*, Aug., 1879). He expresses himself very decidedly as to the benefit he has witnessed from it. He gives gtt. x of the fluid extract, in water, every four or six hours.

UNGUENTUM PETROLEI IN ECZEMA.

An English writer strongly recommends this petroleum product in eczema, for the following reasons: 1. It immediately allays the irritation, and the patient ceases to scratch. 2. It evaporates, and so, unlike most ointments, it does not form a sticky mass, which keeps the irritating discharges in contact with the inflamed skin, and which has to be washed off every time a fresh dressing is applied; and, unlike lotions, it does not render the surrounding tissues sodden. 3. It dissolves the crust of scabs. 4. It is antiseptic.

IODOFORM LOZENGES.

These, as recommended by Dr. Whistler, of London, are—

℞.	Refined gelatine,	1 part
	Mint or fennel water,	2½ parts
	Liquid cochineal,	q.s.
	Glycerine,	2½ parts.

Mix, and make into a base. To a sufficient mass of this—

	Iodoform,	gr. ij.

For one lozenge.

The advantage of this over the ordinary lozenge is that it is flexible, and perfectly unirritating to the mouth; the gelatine affords more relief to dryness of the mucous membrane than other vehicles, and they can be made by any druggist, as no drying oven or special apparatus is necessary.

THE REMOVAL OF MOLES.

For these unsightly marks Mr. B. Godfrey recommends acid nitrate of mercury. His plan is to take a fine-pointed glass tube, and having dipped it in the caustic solution, to dot all round the hirsute mass, upon the healthy skin, where they both join; then to dot points through the mass, like the white squares upon a chess-board, leaving the blank ones to be treated in a similar manner in a fortnight hence. By such a method he prevents too great an inflammatory action setting in, and makes a less scar in the future.

The Bite of the Skunk.

In the *Forest and Stream*, of recent date, is a contribution to the question whether the bite of the skunk is poisonous and will produce rabies. In the West and Southwest of the Mississippi Valley this seems generally believed. A writer from Colorado quotes several instances.

Dr. Cushing, of Trinidad, Colorado, who has, no doubt, seen several cases, gives it as his opinion that the natural bite of the skunk produces hydrophobia—that it does not need to be suffering from rabies itself. He says its bite will kill the victim sooner or later, without fail. Dr. W. L. South, who has had great experience in Texas and New Mexico, says "the bite will fetch the victim some time," meaning that it will sooner or later result in death.

We do not believe this is the case in the eastern States. The skunk is very common in Pennsylvania. We have seen dogs bitten by it, and have known those who hunted it constantly for its valuable skin; but have never heard of any such ill result from its bite, either in man or dog.

A Peculiar Micrococcus in Gonorrhœal Discharge.

In the *Centralblatt für Med. Wis.*, July 12th, Dr. Albert Neisser, of Breslau, announces the discovery of a peculiar form of micrococcus in gonorrhœal pus. It is circular, or oval in outline, not colored by indulin or methylgreen, usually in colonies of ten, twenty or more, surrounded by a membrane, generally found on the upper surface of the pus cells, rarely on the epithelial cells.

Dr. Neisser found these bodies in the gonorrhœal discharges of both sexes, in acute and chronic cases, and in various cases involving the eyes. He believes they are characteristic of the disease, though he does not express himself positively on their pathological significance.

The Ammoniacal Sulphate of Copper in Tic Douloureux.

The *Bull. de Therapeutique* for April states that Dr. Féréol, of the Lariboisière, has met with an amount of success in the use of this almost forgotten remedy in four cases of old and obstinate tic douloureux, that leads him to believe that it is one to which attention should again be drawn. He prefers the fluid form, as in the following mixture:—

℞.	Distilled water,	100	
	Syrup of orange or mint,	30	
	Ammoniacal sulphate,		10 to 15 M.

This to be taken chiefly at meal times, within the twenty-four hours.

If the neuralgia persist, the dose may be gradually increased; and in one case as much as sixty grams per diem was given, but then began to cause gastro-intestinal disturbance. Even in the ordinary dose, after two or three days, fetid breath and a metallic taste may be perceived; but in spite of this, the medicine must be continued at ten centigrams per diem for twelve or fifteen days, especially at meal times.

Improvements Suggested in Lunatic Asylum Organization.

At the close of a searching review of the attempted asylum reform in New York, a writer in the *Journal of Nervous and Mental Disease* presents the following resumé of the changes in asylum organization and management, suggested by the movement for reform now in progress in New York:—

1. To abandon the theory of asylums which considers them chiefly as lunacy cures, established for the benefit of local interests, and to be maintained by lobbying and advertising.

2. To abolish the local boards of trustees, and adopt a system of State management for State institutions, with a single responsible head, in place of the present formal management.

3. To devolve the medical and general supervision of asylums upon the State Board of Charities, which should be composed in large part of physicians.

4. To enact a law similar to that providing for the removal of trustees of savings banks for abuses of trust, so that commissioners or trustees, charged with the supervision of asylums, and neglecting or abusing their trusts, might be summarily removed.

5. The enforcement of a law never carried into effect authorizing the admission of private patients into asylums only when there are vacant places not required for public patients; and the charging of a uniform price of maintenance to both these classes, instead of leaving, as now, the price to be paid by private patients at the discretion of the superintendent.

Plugging the Cervix Uteri for Metrorrhagia.

At a late meeting of the Obstetrical Society of Paris a discussion on the treatment of metrorrhagia was introduced, and among the various manipulative measures that were referred to, preference was given to plugging the cavity of the neck of the womb, which had several advantages over plugging the vagina in such cases. It stopped the blood more effectually, the patients bore it better, and there was less chance of putrid absorption. Each speaker recommended his own plan; but that adopted by M. Panas seems to me the best. It consists of introducing into the cavity of the uterine neck a pledget of cotton wool, rolled up to about the thickness of a goose-quill, and steeped in a solution of the perchloride of iron of the *Codex*, to which is added one part of water, to prevent its caustic effects. This being done, he introduces a ball of cotton wool and places it in the posterior *cul-de-sac* of the vagina, where it not only forms a support to the uterine plug, but it absorbs any liquid that may escape through it, and thus protects part of the vagina (which is covered with the peritoneum) from the corroding effects of the perchloride of iron and the acrid discharges from the womb.

Correspondence.

Partial Inversion of the Puerperal Uterus.

Ed. Med. and Surg. Reporter:—

I was called to see Mrs. S., aged 17, American, on April 11th, 1879, at 8 A.M. Found her in labor, which had passed to the second stage. The os was well dilated, and the head was presenting in the second obstetric position (R. O.A.). She gave a good history and was in good health. She had been in labor about twenty-four hours, but the pains at that time were regular and moderately effective. The child was born at 10.45 A.M., after which I kept my hand on the abdomen over the uterus, to see that it was contracted, and also to stimulate it, if need be, by gently kneading it. In about fifteen minutes the placenta was expelled. As the uterus contracted, the uterine tumor seemed to leave my hand, and, indeed, seemed to be going out through the vagina. At this time blood flowed very freely. I evidently had a case of post-partum hemorrhage, and there was no time to lose. Not having electricity nor ice at my command, I immediately introduced my hand as a tampon, and applied cold water to the abdomen, which, happily for me and my patient, immediately stopped the hemorrhage. On introducing my hand, I found the cervix fully dilated, and the fundus down in the cervix and on the floor of the vagina. I pushed it back to its place and found complete inertia of the cervix; there seemed to be no action in it. I ordered some ergot, which did not arrive for about an hour. I then gave about five and a half milliliters of fl. ext. ergot, and continued on, giving it in two milliliter doses every half hour for two hours; at this time, being about three hours from the time the placenta was expelled, the cervix contracted so as to expel my hand. I then felt that my patient was in a more favorable condition. She had not lost a very great amount of blood, but it came very free until I introduced my hand, after which there was very little hemorrhage. I ordered milk and perfect rest. I saw her again in the evening;

she was doing well; pulse and temperature about normal. On the following morning, April 12th, the pulse was up to 112 per minute, and temperature 99°, feeling very well. She continued on about the same for 12 days, with pulse up, and temperature at no time above 99½°. On the fourth day the lochia started, was normal in appearance and amount, but stopped on the eighth day, and did not appear again. She made a good recovery.

The cause of the trouble, I think, can be traced to the first stage of the labor. When we think of the head pressing against the cervix the length of time it did, we cannot but expect to find the parts destitute of action and almost of life. The os had evidently been rigid and dilated very slowly, if at all, for a time. The long-continued pressure must have overcome the contractile power of the cervix, and left it in a relaxed condition. Then, when the time came for it to contract, it was not able to take part in the contraction with the rest of the uterus. The only muscular fibres that run directly across the fundus are the fibres of the external layer, and by their contracting, with no direct antagonist, as the circular fibres of the cervix did not seem to be acting, it would tend, we think, to draw the uterus more flat across the top, and in that way start inversion, which, I think, was the case here. The hemorrhage, I think, then came from the inverted portion of the uterus, as well as from the paralyzed cervix, and was controlled by the pressure of my hand against the bleeding surface. In regard to the pulse, I think the elevation was due to anxiety on the part of the patient, owing to the fact that she was not, or claimed not to be, looking for the birth until August. As was stated, the temperature was not above 99½°, and most of the time normal. She had a very good appetite, and gained strength very fast. Why the lochia appeared so late and disappeared so soon I am not able to say, as there seemed to be no trouble of any kind, except that involution went on slowly, but naturally and completely.

Stonerville, Pa. J. E. Rigg, M.D.

Frequency of Rigid Os Uteri.

Ed. Med. and Surg. Reporter:—

In your issue of Aug. 2d Dr. Simpson, of Thompson, Pa., gives us his experience in treating a rigid os. I have no fault to find with his treatment, but I think his arithmetic is out of tune.

He informs us that that obstinate organ has been "rigid" in 167 of the 218 cases he has recorded, and that he has treated them all with tartar emetic.

Is it not probable that a *rigid examination* of these cases would have shown nearly every one of them to have been no such thing, thereby saving his patients much unnecessary nausea?

In nearly double his number of cases I have not met with a dozen complicated with this trouble.

If this is the kind of medical literature we pay for, I am constrained to exclaim, in the language of the small boy, "Give us a rest!"

New Hampton, Iowa. A. Babcock, M.D.

[It is well to be temperate in criticism. If in over 400 cases of labor Dr. Babcock has not met a dozen cases of rigid os, it is either because his experience is wholly unique, or because he did not know it when he met it. Dr. Playfair speaks of this complication as "one of the most frequent causes of delay in the first stage" (Midwifery, p. 339). Dr. F. Barnes mentions it as "the most common cause of obstructed labor" (Manual of Midwifery, p. 151). Dr. Albert H. Smith says of one form of it, "I am constantly meeting with such cases" (Medical and Surgical Reporter, vol. xxxvii, p. 121). We recommend Dr. Babcock to read medical literature more closely, and we believe he will become better satisfied with the kind we give him.—Ed. Reporter.]

Case of Strychnine Poisoning.

Ed. Med. and Surg. Reporter:—

In reading the report of Dr. Chaplain's case of strychnia poisoning, in the Medical and Surgical Reporter for Aug. 2d, 1879, one must suppose the Doctor either failed to report the means employed for the relief of his patient or put forth no efforts to save his life, except the ineffectual effort to administer medicines by the mouth. In either case I think he has made an omission not readily excusable. In the first place, proceedings and treatment in reported cases should always be mentioned, not only for the enlightenment of those who peruse them, but for the clinical advantages which may be derived from them. If the Doctor employed no means to save the life of his patient (which I infer from his report), I would say he failed to do his duty, from the fact that there are a number of well authenticated cases on record where the same, or even larger, doses of the fatal drug were swallowed, with spasms developed (identical with the Doctor's case), where recovery has followed the various means employed. For instance, Dr. Dresbough's case, at Tiffin, Ohio, where the patient was alarmingly ill from grs, iij of strychnia swallowed, and where there was complete relief obtained in less than fifteen minutes, by ʒ ij of chloroform, taken internally. (See *American Journal of Medical Sciences*, xix–546.) Cannabis Indica has proven effectual in a case reported by Dr. S. A. M. Williams, Chicago. The man had taken five grains of strychnia; was violently ill; under drachm doses tr. cannabis indica, repeated every five minutes, then gradually giving the dose at longer intervals, etc., complete recovery occurred in forty-eight hours. (Medical and Surgical Reporter, Feb. 2d, 1867.) So a number of other cases could be cited, in which recoveries from strychnia poisoning have occurred under the timely use of antidotes.

Reasoning from the above and other recorded cases, and from the physiological effects of strychnia, I think, in a case like the one reported, inhalation of chloroform, ether, or nitrite of amyl should have been resorted to at once, with

the hope of overcoming convulsions, thereby enabling antidotal medication by the mouth.

Hypodermic medication would have been available, at all events, in spite of, and perhaps with the effect of, breaking up the convulsions in which the patient died, in which case further treatment would have suggested itself, with probable recovery of the patient, and another recorded victory for science. Had the case ended fatally (as it did), the Doctor could have felt that he had done his duty, and the profession at large could have felt that science had been defeated in a noble, but unfair, fight.

The fear that the perusal of the Doctor's report might leave an impression on the minds of some readers of the REPORTER that nothing should be attempted in such cases, prompted this communication. GEO. P. YOST, M.D.

Loganville, Pa.

[We have inquired of Dr. CHAPLAIN in reference to his treatment, and he replies as follows:—]

The case of S. D. Fletcher was reported more especially to give the quantity of strychnia swallowed, and the time elapsing before death. As regards treatment, it was absolutely nothing. An emetic was first ordered, which, in all probability, would have proved useless, since the strychnia had been taken twenty minutes before, on an empty stomach, and doubtless had already passed out of that organ. An attempt was also made to administer whisky. But when a powerful man, as this one was, determines that nothing shall be done to save his life, and resists to the utmost your efforts to relieve him, of what avail are the services of the physician? Neither hypodermic nor anal syringes were at hand, and could not be procured before the death of the patient.

L. CHAPLAIN, M.D.

Treatment of a Case of Anasarca by Punctures in the Lower Extremities.

ED. MED. AND SURG. REPORTER:—

Mr. A. L. F. was an unmarried man, of about thirty-three years of age, rather irregular in his habits and morals, but generally healthy and robust. At the time I was called to see him (April 12th, 1879) he had been treated by an irregular physician, for dropsy, by the administration of powerful hydragogue cathartics, with the object, no doubt (on general principles), of producing watery evacuations. In spite, however, of this heroic treatment, anasarca gradually succeeded upon dropsy, until the extremities were extensively distended, and the amount of fluid contained within the cavity of the abdomen was sufficient to produce mechanical obstruction to the breathing. Following the advice of one of my former professors while a student at McGill University, I resolved to make a sufficient number of openings through the skin in the lower extremities to favor the escape of a portion of the fluid. This was done on the 15th of April, five punctures being made with a Symes' knife, in each limb, below the knees. I had come to the conclusion, from the history of the case and the objective symptoms, that this abnormal condition of the body and limbs was caused by obstruction to the renal circulation, through congestion of the tubules, brought on by exposure to cold; consequently, under this conviction, I placed the patient under a constitutional treatment by diuretics and tonics. As a diuretic, was given—

℞. Fluid extract digitalis, ʒ ij
" " scillæ, ʒ ij
Spirit. ether. nitrosi, ʒ ij
Aquæ puræ, ad, ʒ iv. M.

SIG.—A small teaspoonful every four hours.

As a tonic, was given—

℞. Ferri et quiniæ citratis, ʒ ij
Acid muriatic. diluti, ʒ iij
Glycerinæ, ʒ ij
Aquæ aurantii, ad, ʒ iv. M.

SIG.—A teaspoonful every four hours.

I visited the patient every second day subsequent to the operation, and was extremely gratified with the result, which seemed in every way favorable. At the end of the eighth day the amount of serum that had been discharged was estimated at over two gallons; nor was I disappointed in the excessive prostration which supervened. It was fortunate for the patient that so gradual a process of evacuating the serum was devised, as, had it been more sudden, I do not believe that the patient would have rallied. Under the combined administration of tonics and diuretics, in a few days the patient expressed himself as feeling much more comfortable than he had been in weeks previously. The anasarca had nearly all disappeared, and the breathing was not obstructed. The incisions made by the knife were readily healed by bandaging and the application of an ointment made of subacetate of lead, camphor and opium. I have alluded to this case in so far as it relates to the operation of puncturing the lower extremities in the treatment of anasarca. The relief afforded in this case warranted the operation, and under similar circumstances I would not hesitate in resorting to the operation again.

A. O. STIMPSON, M.D., C.M.

Thompson, Pa., August 17th, 1879.

NEWS AND MISCELLANY.

Epidemic Disease.

The yellow fever continues in Memphis, from 20 to 25 new cases occurring daily. It is believed, however, not to be epidemic in any other of the Southern cities. Houston declared quarantine against Galveston last week, but the authorities of the latter city insist there is not a single case of fever there.

The following despatch from Warner P. Sutton, United States Consul at Matamoras, to the Secretary of State, is dated at Brownsville, Texas, August 10:—

Reliable information from Tampico, August 1st, says: "We have a yellow fever epidemic worse than New Orleans last year. People die like flies. Quarantine at Bagdad against Tampico still efficient."

The official statement of the mortality of

Havana during the month of July shows 475 to have died from yellow fever, and a total number of 1151 deaths against 1386 deaths in July last year, a decrease of 235.

Dr. J. W. Compton, of Evansville, Ind., gives some statistics of an epidemic of scarlet fever which had prevailed there since January last, remarkable for its continuance rather than its severity. The public schools continued fully attended, against the protest of Dr. Compton, who ascribes to that cause the maintenance and propagation of the disease. In a population of 40,000 there were 570 cases and 121 deaths. Ratio of cases to population, 14.25 per 1,000; of deaths to population, 3.02 per 1,000; of deaths to number of cases, 21.23 per cent.

Smallpox of a malignant type has broken out at Lanse St. Jean, on the Saguenay, Canada, and is raging very badly in the district, where there is no medical attendance.

Curious Relation of Religious Belief to Epidemics.

The Montreal *Witness* states that diphtheria is more prevalent among the Protestant section of Montreal community than among the Catholic. It is not a mere coincidence, nor is it of a temporary character. A study of the health statistics of Montreal for several years past reveals the same state of things. It is the more peculiar, inasmuch as the general death rate is much higher with the Catholics, particularly so in contagious diseases, and conspicuously so in the case of smallpox. But these admit of explanation. The only solution of the problem seems to be that the bulk of the Protestant community reside in the upper part of the town, where the drainage is less perfect than in the lower town.

British Medical Association.

The Association met at Cork on the 5th inst. We have received a full report of the proceedings, by the kindness of Dr. Laurence Turnbull, of this city, one of the invited guests of the Association. It will appear in our next number.

Items.

—It is suggested in a Western newspaper that there shall accompany the publication of the next census returns a list of persons in the United States who have lived their hundred years—the centenarians to be hunted up by the postmasters and the names to be preserved at Washington.

—The health authorities of New York city have been inspecting the tenement houses. They find that in many of them whole families sleep in a single room, where there is not a window, and no other ventilation than such as the door affords; the cellars and adjacent areas usually answer as a receptacle for dead cats; nobody ever seems to pay any attention to burst waste pipes, and sewer gas fills most of the rooms day and night.

—The meeting of the Canada Medical Association has been postponed to the second Wednesday in September.

Personal.

—The President has appointed Philip I. Wales, M.D., of Maryland, Medical Inspector U.S.N., and Chief of the Bureau of Medicine and Surgery, Vice J. Winthrop Taylor retired. Dr. Wales has at times contributed valuable articles to the MEDICAL AND SURGICAL REPORTER.

—Dr. William O. Mosely, Jr., a young physician of Boston, met his death on the Matterhorn, in Switzerland, Aug. 15th. He had made the ascent, and was descending, when he slipped and fell over a precipice, killing him instantly.

—The Cleveland physicians referred to on p. 66, Drs. Schneider and Smith, are homœopathic brethren.

QUERIES AND REPLIES.

Codex puts the following:—"A. is a regular practitioner; B. is a homœopath. B. is very deaf, and A., on invitation, sometimes accompanies him to examine cases of heart or lung disease; does not consult, prescribe, or charge or receive a fee; simply lends B. his ears. Does he violate the code?"

ANS.—The patients and their friends seeing the two physicians together, will regard them as associated, and therefore will believe the regular physician countenances and supports the practitioner of the exclusive dogma; hence, it seems to us, the general effect will be as detrimental and as contrary to the Code as a deliberate and full consultation.

Dr. *K. R., of Ky.*—Creosote has been occasionally employed in typhoid fever. Dr. Pecholier, of Paris, reported some cases about ten years ago, believing them very favorable. We have no personal experience with it.

Franciscus.—It is probable that the insanity of Charles VI, of France, was due to a sun-stroke. The child of the "woman of Shunem," in the Old Testament, is another historical example of the same accident.

Dr. *William.*—Second-hand medical books sell very low; you could not get much for them in this city.

Dr. *Al. K. M.* asks—"Is it proper for a physician to prescribe by letter for patients he has never seen? I do not mean through another physician, but directly."

ANS.—Yes it is. The most respected men in the profession do it. Nevertheless, it is capable of great abuse.

DEATHS.

BROWN.—At Hartford, Conn., on Saturday, Aug. 9th, Dr. Chauncey Brown, of Farmington, Conn., aged 75 years.

BUCKINGHAM.—In this city, on the 25th ult., George B. Buckingham, youngest son of Dr. T. L. Buckingham, in the 20th year of his age.

CHAPIN.—In New York, on Saturday, Aug. 2d, 1879, Reuben S. Chapin, M.D., aged 61 years.

CHURCH.—In New York, on Thursday, Aug. 7th, Dr. Austin Church, in the 81st year of his age.

PETERSON.—In this city, on the 23d ult., Blanche, wife of Dr. Robert E. Peterson.

ROWLAND.—In New York, suddenly, on Thursday, Aug. 7th, Charles Rowland, M.D., in the 80th year of his age.

SMYTH.—In this city, on the 24th ult., Francis G. Smyth, M.D., aged 35 years.

YOCUM.—In this city, on the 21st ult., of typhoid fever, Benjamin B. Yocum, M.D., in his 34th year.

DOCTOR RABUTEAU'S

(Laureate of the Institute of France.)

DRAGEES, ELIXIR & SYRUP

Of Proto-Chloride of Iron.

"The experiments made in the hospitals of Paris have demonstrated that *Dr. Rabuteau's Dragees, Elixir and Syrup* regenerate the red globules of the blood with a rapidity never observed with the use of the other ferruginous preparations. These results have been proved by the various *Compt-Globules.*

"The ferruginous preparations of *Dr. Rabuteau* do not cause any constipation, and are perfectly tolerated by the weakest persons."—*Gazette des Hospitaux.*

Dr. Rabuteau's Elixir is prescribed when some difficulty is experienced in swallowing the Dragees; it is especially adapted to weak persons, whose digestive functions need strengthening or stimulating.

Dr. Rabuteau's Syrup is especially prepared for children, who take it readily, because of its agreeable taste.

MEYNET'S

DRAGEES OF COD-LIVER EXTRACT.

Careful experiments have established the fact that the **EXTRACT OF COD LIVERS** contains very valuable properties, which render it superior to the ordinary cod-liver oil. It is composed principally of *Gaduine*, large proportions of *Iodides, Chlorides, Bromides, Phosphoric Acid, Lime, Soda* and *Ammonia*, and especially *Propylamin*, all of which enter, but in very small proportions, into cod-liver oil.

These dragees of pure cod-liver extract take the place of cod-liver oil, and have been used with eminent success by medical celebrities of Europe in cases of *Scrofula, Rheumatic Affections, Rachitism, Phthisis*, and in all cases where a propylamic medication is indicated.

MEYNET'S DRAGEES are sold in bottles containing 100 dragees. Dose, 2 to 6 a day. Each dragee is equivalent to two tablespoonfuls of cod-liver oil.

MEYNET'S GRAINS are small granules intended for children. 10 are equivalent to 1 dragee.

E. FOUGERA & CO., New York, Agents for the U. S.

RIGOLLOT'S MUSTARD PAPER.

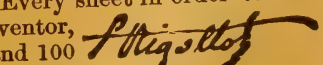
Is one of the most important and useful discoveries of the age, but it is not (as certain dealers of bad faith pretend) a preparation that any one can make, for it is not manufactured with a mustard that every one can buy.

RIGOLLOT'S MUSTARD PAPER.

Is the invention of Mr. P. RIGOLLOT, who is the exclusive owner; it is the only preparation which has been adopted by the civil and military hospitals and the armies and navies of France and England, and which has obtained a medal at the Centennial Exposition at Philadelphia. All other mustard plasters or leaves of whatever name, are but imitations of the original

RIGOLLOT'S MUSTARD PAPER.

Physicians will find it the most reliable sinapism, prompt and certain in its action, and will therefore always prescribe it. Every sheet in order to be genuine must bear the annexed signature of the inventor,



Sold in tin boxes containing 10 sheets, also 25 and 100 sheets, by all respectable chemists throughout the world.

E. FOUGERA & CO., Agents,

NEW YORK.

NEW REMEDIES.

RECENTLY INTRODUCED BY US.

RHUS AROMATICA.

Highly recommended in the treatment of diabetes and other diseases of the genito-urinary organs, viz.: Hematuria, enuresis (in both old and young), uterine hemorrhage, and as a local application in leucorrhea; also in atonic diarrhœa and dysentery, and more especially summer diseases of children.

See article by Dr. McClanahan, in the April number of *New Preparations*.

We offer this new remedy in the form of a fluid extract from the fresh bark of the root.

FOLIA CAROBÆ.

JACARANDA PROCERA (SPRENGEL). This new drug, from Brazil, is now attracting the attention of the profession in Germany, as a valuable and effective anti-syphilitic. It is said to possess alterative, diuretic, sudorific and tonic properties, to a marked degree, especially in the latter particular. Hence its application to the treatment of syphilis in all its forms.

The Carobæ may be continued advantageously with Iodide Potassium in cases distinguished by pains in the limbs. It is indicated in the cure of old syphilitic ulcers, to which it may be applied topically.

CASCARA SAGRADA.

RHAMNUS PURSHIANA. This is the bark of a tree indigenous to northern California and Oregon, known botanically as the Rhamnus Purshiana. It has long been used on the Pacific Coast, among the Indians and old Spanish residents, as a remedy for habitual constipation and other disorders of the alimentary canal. Many physicians write to us that they must have the Cascara *at any price*, as it has proved invaluable in their practice.

We cannot too strongly caution physicians and druggists to specify **"P., D. & CO.'S,"** if they desire a preparation of the *true* drug, Rhamnus Purshiana.

COTO BARK.

The tree from which this bark is derived is a native of Brazil and Bolivia, though as yet we *cannot locate it botanically*. Coto Bark was first tested clinically by Prof Gietl, of Munich (Germany), who considered it a specific for diarrhœa in its various forms. Dr. Riecker, of Stuttgart, concurred in this. Prof. Baetz, of Tokio, Japan, in the *Centralblatt*, recommends it for malignant cholera In Bolivia it is used for diarrhœa, colic, and neuralgic toothache, and externally in rheumatism and gout. It has been also employed in the sweating of phthisis, and typhus, catarrhal diarrhœa, gastric catarrh, pneumonia, uterine colic, acute articular rheumatism, cholera, cholera morbus, dysentery, night sweats, etc.

FIVE FLOWERED GENTIAN.

GENTIANA QUINQUEFLORA. Among the many substitutes for quinine this plant is one of the most valuable. In many cases where quinine and other antiperiodics have proved futile, this remedy has been found very efficacious. In combination with hydrastis, it has been found an excellent tonic in depraved conditions of the digestive apparatus, increasing the biliary secretions and acting as a stimulant to the excretory organs. In fevers, in combination with gelsemium, and in derangement of the biliary organs, in conjunction with leptandrin and podophyllin, it seems to increase the action of those agents.

GRINDELIA ROBUSTA.

This remedy has been successfully employed in asthma, bronchial difficulties, iritis, vaginitis, and other diseases of the mucous surfaces. In combination with Yerba Santa it has also been found specially efficacious in bronchial affections. It is well known that many of the varieties of this family bear so close a resemblance to each other that it is difficult to distinguish between them, and the Squarrosa and other varieties are hence often unwittingly substituted for the Robusta. Our own supply is gathered for us under the direction of a competent botanist, and is known to be genuine.

DESCRIPTIVE CIRCULARS.

We shall be happy to furnish upon application descriptive circulars giving the botanical history and therapeutical application of New Remedies recently introduced by us. We will also send, if desired, our price list, giving names and prices of nearly two thousand articles manufactured by us.

☞ *Send stamp for Price List and Circulars described above.*

PARKE, DAVIS & CO.,

Always specify Parke, Davis & Co.'s. **DETROIT, MICH.**

Our goods can be procured of Messrs. W. D ELLIOT & Co., Philadelphia; LEHN & FINK and WALTER ADAMS, New York; SMITH, DOOLITTLE & SMITH, Boston; and of druggists generally throughout the West.

WYETH'S

DIALYSED IRON.

(FERRUM DIALYSATUM.)

A Pure Neutral Solution of Peroxide of Iron in the Colloid Form. The Result of Endosmosis and Diffusion with Distilled Water.

PREPARED SOLELY BY

JOHN WYETH & BRO.,

PHILADELPHIA.

This article possesses great advantages over every other ferruginous preparation heretofore introduced, as it is a solution of iron in as nearly as possible the form in which it exists in the blood. It is a preparation of invariable strength and purity, obtained by a process of dialysation, the iron being separated from its combinations by endosmosis, according to the law of diffusion of liquids. It has no styptic taste, does not blacken the teeth, disturb the stomach, or constipate the bowels.

It affords, therefore, the *very best* mode of administering

IRON

in cases where the use of this remedy is indicated.

The advantages claimed for this form of Iron are due to the absence of free acid, which is dependent upon the perfect dialysation of the solution. The samples of German, French and American Liquor Ferri Oxidi Dialys. which we have examined give acid reaction to test paper. If the dialysation is continued sufficiently long, it should be tasteless and neutral.

Our dialysed Iron is not a saline compound, and is easily distinguished from Salts of Iron, by not giving rise to a blood-red color on the addition of an Alkaline Sulpho-Cyanide, or a blue precipitate with Ferro-Cyanide of Potassium. It does not become cloudy when boiled. When agitated with one part of Alcohol and two parts of Ether (fortior), the Ether layer is not made yellow.

Physicians and Apothecaries will appreciate how important is the fact that, as an antidote for Poisoning by Arsenic, Dialysed Iron is quite as efficient as the Hydrated Sesquioxide (hitherto the best remedy known in such cases), and has the great advantage of being always ready for immediate use. It will now doubtless be found in every drug store to supply such an emergency.

Full directions accompany each bottle.

Physicians will find our DIALYSED IRON in all the leading drug stores in the United States and Canada.

It is put up in bottles retailing for **ONE DOLLAR**, containing sufficient for four months' treatment Large size is intended for hospitals and dispensing. Retail at $1.50. Price Lists, etc., sent on application.

REPORT OF A CASE OF STRICTURE OF THE MALE URETHRA (TRAUMATIC), WITH DILATATION, PUNCTURE OF THE SAC AFTERWARD, AND OPERATION, WITH GOOD RESULTS.

BY D. PORTER MORGAN, M.D.,
Of Clarksburg, W. Va.

Case.—June 6th, 1878. Drs. J. M. and J. W. Bowcock, Allen Gittings and myself went several miles into the country to see this patient, Dr. J. M. Bowcock having received a note from an old country physician, asking him to come "prepared to operate on the penis."

The patient, Jas. R———, aged 17 years, was kicked by a horse, on the under surface of the erect penis, two years before, from which stricture supervened (there was no external wound), which was followed by dilatation of the canal of the urethra, commencing about 1¾ inches from the meatus, and extending almost to the bulbous portion. The boy informed us that after the accident he suffered intense pain many days, and was experimented on by a host of so-called "doctors," among the rest the "Indian" (Negro) doctor. They all tried a number of times to pass a silver *female* catheter (this seems to have been the entire stock of genito-urinary instruments) into his bladder, but failed, of course. The boy asked one of these *intelligent* and *learned* gentlemen for a silver probe which he saw, having obtained which, he passed it into the pouch or cul-de-sac, and by this means was enabled, after a few days, to empty his bladder and thus relieve himself. From the time of the accident until a day or two since, he tells us, he was enabled to empty his bladder pretty well by forcing his urine into this pouch, and then using firm pressure with his hands, could empty the pouch. He did very well until June 4th, 1878, when he found it impossible to expel any urine whatever by any means known to him. His demand becoming urgent, he informed his father, who immediately placed him upon a horse and carried him to the nearest "doctor," who kindly informed him that he knew but little of the urinary organs, and that he would not undertake even to pass a catheter. The father then carried him to West Milford, to old Dr. Drew, who immediately punctured the pouch, inserted a female catheter and relieved the boy for the time being, after which he wrote the note aforementioned to Dr. Bowcock.

We found him a well-grown boy, whose general health was pretty good, in the following condition: A stricture, before mentioned, 1¾ inches from the meatus, through which we found great difficulty in passing, but finally passed a Simpson's sound or uterine probe. This pouch or sac was about 12 inches in circumference, firm, solid, and to external appearances indicated that there might possibly be fibroid thickening. Dr. D. wanted us simply to amputate the penis *in toto*, and thus end the matter, which proposition we, of course, immediately declined. We decided, inasmuch as there was already a fistulous opening into the urethra, to lay open the pouch and see what more could be done for this unhappy lad. At this stage it was found necessary to remove the patient, previous to operating, a distance of six miles, to a point at which he could be properly nursed. Having done so, we placed him on a bed and gave him a free supply of whisky; he

declined chloroform. We opened the pouch by a longitudinal incision along the course of the urethra; we found the integument and corpus spongiosum thickened greatly. The pouch contained a considerable quantity of urine, a great deal of white sand, some mucus, etc. After laying it open, we easily and completely broke up the anterior stricture, but found it very difficult to find the distal continuation of the urethra; in fact, there were such an immense number of little depressions or sacules in the mucous membrane, each looking as if it were the continuation of the urethra, that we were long in finding the true one, and finally, when almost worn out, after three and a half hours of hard work and manipulation, we succeeded, by having the patient force a little water from the bladder, which he did, in a stream not larger than a cambric needle. This found, we experienced very great difficulty in introducing any instrument at all, but finally succeeded, after very great effort, in passing the sharp point of a little silver probe, which we quickly followed by a fine grooved director, then taking a sharp bistoury we slit the opening and passed a No. 8 flexible catheter through the meatus into the bladder, tied it there, closed the external wound by interrupted sutures and adhesive straps, put the boy to bed, gave him morphia sulph., gr. ½, and left him. When seen a few days after, it had mostly healed by first intention. I cauterized it on the eighth day, and about the twelfth day Dr. Bowcock freshened the edges, and so far as we know he recovered entirely. At the end of three weeks the flexible catheter became rough and irritable. We sent him a new one, which he introduced himself, and which he retained until able to abandon it. He is reported quite well.

TWO CASES OF PUERPERAL CONVULSIONS.

BY J. W. HAMILTON, M.D.,
Of Brooklyn, N. Y.

For the purpose of recording my own convictions on this serious complication of labor, I desire to describe the only two well marked cases that have occurred within my personal observation during a practice of nearly twenty-five years. Beside this, the treatment adopted in the cases referred to fairly represents that in vogue at the respective periods named.

The first case occurred in the city of Philadelphia, in the summer of 1855, and only a few days after my sign for the first time adorned my window shutter. I found my patient, a healthy, robust, young married woman, a primipara, lying on a lounge in the dining room, wrestling in the throes of a violent convulsion. Upon inquiry I learned that the hour of her expected accouchement was nigh, and that she had had several convulsions on the same morning, prior to my arrival. Thanks to the pointed and graphic teachings of the late Prof. C. D. Meigs, the subject had been so rooted and grounded within my nature, that I at once recognized the condition of things, and fully appreciated the gravity of the trouble with which I had to deal. No one who attended his lectures during the years of 1853, 1854 and 1855, ever left the amphitheatre in doubt as to his duty in such an emergency. In this case the only question was who should discharge that duty? Conscience and duty said bleed, prudence said wait, and let some one else do the work. Prudence won, and I at once dispatched a messenger for my friend, Dr. Arthur McWhinney. In the meantime the patient had been removed to an upper chamber. Convulsion after convulsion followed each other in rapid succession.

Dr. McWhinney promptly responded to my call. Taking out his lancet, after having bandaged the arm, it was only the work of a moment, and the next a full, round stream came gushing from the median basilic. About the quantity taken I do not now remember, but the effect was magical. The convulsions were at once broken. She opened her eyes and glanced wildly around the room, without, however, seeming to recognize anything of the surroundings. The flow of blood was at once stopped, the arm properly bandaged, and Dr. McWhinney left. Before leaving he had advised me, in the case of a recurrence of the convulsion, to remove the bandage and again allow the blood to flow freely. Nor had I long to wait, for again she was in a convulsion (although in a greatly mitigated form), and again was it arrested by the flow of blood. In the meantime the uterus was doing its duty efficiently. The pains, without interruption, were coming with increased force, and the head rapidly descending. Finally, as if nature had been husbanding her resources for the last great struggle, and in the midst of a convulsion, the most terrible since the first bleeding, the head emerged from the vulva, the child was removed, and this was the last convulsion. In a few moments consciousness returned, but the past was an absolute blank, and when the child was held up to her view she was incredulous. She had not realized its birth, and knew nothing of the pain through which she had just passed.

She made a speedy recovery and the child did well.

The next case occurred in the city of Brooklyn fifteen years later. Like the first, it was a primipara, young, healthy, well nourished, and full of courage. She was taken with convulsions soon after my entering the house; whether she had any before my entrance I do not recollect. As in the first case, we met for the first time at the bedside. The usual temporizing policy, so much in vogue at this time, was pursued; chloroform, verat. viride, etc., were freely administered. A consultation was called. Everything was done save the right thing, and our patient died. Just before breathing her last she was delivered of twins, stillborn, at about eight months' term. Had we been governed by that high sense of professional duty that should characterize every man's work, irrespective of outside clamor, and bled our patient, I believe we should have saved a life. It is just the consciousness of these mistakes that modify the pleasures attending the successes of a professional life. While standing at the bedside of the dead, I mentally resolved that, should it ever again be my fortune to be called to a similar case, no earthly power should interpose between me and what I conceive a plain professional duty. She should have the benefit of a full, free venesection. This being done, with such auxiliary measures as might suggest themselves, I should consider my patient comparatively safe; in default of it, I should feel no sense of security.

In conclusion, I will only add, that if the more youthful members of the profession, finding other means failing them, will give the one herein suggested a single trial, not faintly and grudgingly, but with that confidence born of faith and fair judgment, I believe they may have ocular evidence of its advantage over every other mode of treatment.

APPEARANCE OF THE TONGUE IN DISEASE.

BY JOHN A. HENNING, M.D.,
Of Red Key, Ind.

By request of some of your readers, I continue the further consideration of this subject, from No. 5 of this volume, page 99.

1. The *elongated* and *pointed* tongue invariably indicates irritation and determination of blood to the stomach and intestines. The extremities are often cold. It is also associated with excitation of the nerve centres.

This tongue is often found, but more especially among children. The indications are to allay irritation and divert the blood from the stomach and bowels. We should be very careful how we make our prescription in such cases, as, if we give an irritant cathartic it invariably aggravates the disease.

2. The *pinched* and *shrunken* tongue indicates atony of the digestive organs, often found in dyspepsia and kindred diseases. The treatment is plain, the pathological conditions being evident at a glance, from the appearance of the tongue.

3. The coating (*saburra*) or fur should be well studied. It may be greater or less in thickness, dry or moist, or clammy, more accumulated at the posterior portion.

It is said that when the tongue is heavily coated at the base, with a deep yellow coat, the liver is at fault. This is not always the case; and from my observation, more often not the case. I have seen cases of jaundice with a white-coated tongue. Tobacco chewers nearly always have a yellow-coated tongue, and their liver may be sound.

4. The *dry* tongue has a very important significance. When we have patients who are suffering from some form of fever, pneumonia, or any other acute disease, with such a tongue, they are in danger, and require close attention. In such cases nutrition and assimilation are suspended, and food cannot well be taken, and if taken cannot be properly assimilated. When given, it should be in fluid form, and always above the temperature of 100°; and of a character nutritive and digestible. The digestive organs can do but little work, yet proper food given at proper intervals does good; but these organs need all the rest they can get until the disease is subdued.

Dryness of the tongue is also associated with vascular excitement, and particularly with excitation of the ganglionic and nerve centres. Hence the arrest of secretion and this dryness. Here we readily read the state of the *nervous system*.

In many cases the sympathetic nerve is not only excited and irritated, but there is involuntary contraction of muscular tissue, thus suspending the secretions of the several organs. The indications are proper sedatives for the vascular excitement, and diaphoretics for contractions or excitement of the nerves, associated with other proper treatment. By this course we shall soon see our patient with a moist tongue, and some of the secretions reëstablished.

5. Often the tongue changes in the disease, from the dryness above referred to to a brown or black color, with sordes about the teeth. The common idea is that the system is in a typhoid condition. This is true, yet it undoubtedly means, also, that the *blood* is in a *septic* condition; a very important fact for us to know. Then our best antiseptics should be given, with stimulants and tonics.

Thus we can readily read, from the appearance of the tongue, the condition of the digestive organs, function of nutrition and assimilation, the condition of the nervous system and the state of the blood. Of course, we must take all other symptoms into consideration; yet the appearances of the tongue, as pointed out, seldom fail in giving us, at a glance, valuable information as to the true condition of the system.

Hospital Reports.

COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

Clinical Lecture, delivered by Professor T. Gaillard Thomas.

Reported for the Medical and Surgical Reporter.

DISEASES OF WOMEN.

Case 1.—Stenosis of the Os Internum—Endometritis and Sterility.

Gentlemen:—The first case which I show you to-day is a very important one, for the reason that it is so exceedingly simple. Sometimes, you know, we have cases which are important on account of their comparative rarity; so that it is a matter of consequence that you should note them with sufficient care to be able to recognize them afterward in actual practice, in case you should not have the opportunity of meeting with another of the same kind during your college course. Such a case was that of the old lady from Long Island, who was here last week, suffering in such a marked manner from the polypus hanging from her urethra, and who, unfortunately, has neglected her promise to return and have it removed to-day. Everything, I may say in passing, had been prepared for the operation; but this is one of those little disappointments to which we have to get accustomed here, on account of the uncertainties in regard to patients in such a clinic as this. The present case, however, is one of a class which you will meet over and over again in practice. They will, in fact, pursue you, so to speak, constantly; and you will find it a very difficult matter to be able to mark them on your books "discharged cured." They are perfectly easy cases so far as diagnosis is concerned; but their successful treatment will demand your most careful attention and no small amount of patience.

The patient's name is Margaret W.; she is a native of the United States, and twenty-six years of age. She has been married six years; but has never been pregnant. Here, then, at once, is the evidence, or almost the evidence, of something wrong about the woman.

How long have you been sick? "For six years." (Or, in other words, ever since her marriage.) What has annoyed you chiefly? "My stomach often swells up." (In order to get rid of this symptom at once, I will explain here that I found this "swelling up" due merely to tympanites. It has been a source of considerable anxiety to the patient, and she, no doubt, came here to-day with the idea that she was affected with some dreadful sort of tumor.) What else do you complain of? "I have the whites very bad." Do you suffer all the time from this? "Yes, constantly." What else? "Constant backache." Is there anything else that troubles you? "My feet sometimes swell, and I have pains down the limbs." Do you have much pain during your monthly periods? "I suffer terribly then." Does the pain come on before the flow, or after it has commenced? "It begins at the same time as the flow." And how long does it continue? "As long as the flow lasts." Then, when the flow stops you are free from pain? "Yes, except some headache for a little while." That is all that you complain of, is it? "Yes."

Now, gentlemen, in connection with this case, it is well to remember what I recently told you in my didactic lectures, that in the diseases peculiar to women we are constantly meeting the same general symptoms in almost all sorts of cases, and yet when we come to find out by physical examination what is the actual state of the pelvic organs, we ascertain that exactly the same symptoms may be due to at least ten or twelve different pathological causes. In this patient, as elicited by the history, we find a great many of the ordinary symptoms of uterine disease. What are they?

1. Severe and constant backache.
2. Constant leucorrhœa.
3. Violent pain during the menstrual period, beginning and ending with the discharge of blood.
4. Sterility.
5. Tympanites.
6. Headache, coming on about the time of the menstrual period, and continuing for some little time after it.

Let us, then, endeavor to find out what pathological conditions give rise to such a train of symptoms in this particular instance. It is well always to bear in mind that we do not make uterine examinations for the sake of discovering some peculiar fibroid, or some other rare and curious condition, but merely for the purpose of seeing whether it is not possible by this means to get hold of the key to the various symptoms in each individual case. The only question that should present itself, in any instance, to the examiner, ought to be, Can I discover anything which will satisfactorily account for the particular phenomena here presented? Now, in this case, the physician may, in his examination, perhaps, discover that the patient has a floating kidney. That would be a rare and curious fact. Or he might find that she was the subject of abdominal aneurism. That, too, would be very

rare and interesting. But neither of these pathological conditions would offer any explanation of the various symptoms complained of, and the medical attendant, unless he find something else abnormal, would not have got at the real facts of the case. Let me tell you, then, what was discovered here when the examination was made.

As soon as my finger reached the os uteri, I recognized it as that of a multiparous uterus. It was not specially small for a uterus of this character, but still quite small enough to indicate that the woman had never been impregnated. With two fingers of one hand at the cervix, and the other hand upon the abdomen, I was enabled to move the organ about freely in every direction, and I could also get my finger behind the uterus with the greatest facility. While I was making these manipulations, however, I was struck with the peculiar lubricity (there is no other word to express just what I mean) of the whole vaginal canal, as elicited by my fingers in the vagina, notwithstanding the fact that they were smeared with soap. I furthermore detected that there was a plug of something hanging from the cervix, which was sufficiently firm to be rolled between the fingers. Finally, I noticed that nothing was to be discovered about the ovaries.

The patient's position was then changed from the back to the side, and Sims speculum introduced; the posterior wall of the vagina being lifted up by the blade of the instrument, and the anterior wall held out of the way by means of the ordinary depressor. It then became evident that the plug hanging from the cervix uteri, which was of the color of the white of an egg, was composed of mucus; and as I touched it with the uterine sound it acted very much as a polypus might have done under the circumstances. Then I grasped it with a pair of ordinary dressing forceps and drew it out as far as the vulva without its becoming detached from the cervix. Next I directed a strong jet of water from a syringe upon it; but still it remained *in situ*. Finally, I took a small piece of dry sponge (it is important that the sponge should never be wet when used for this purpose), and, placing it in an ordinary sponge-holder, forced it up into the cervical canal. Now, twisting it around, I succeeded in breaking the hold of the tenacious mucus upon the arbor vitæ of the cervix, as it is called, and removed the entire plug, which measured six or eight inches in length altogether. At last the os was perfectly clear; and this method is, in my opinion, the only way of removing such a plug of mucus with any certainty.

By this time I had begun to arrive at a diagnosis. What was the matter with the patient? Well, for one thing, she certainly had cervical endometritis, and, in all probability, corporeal endometritis also. Now, have we got at the key of the case? Let us see. Can such a condition as this prevent conception? Undoubtedly; and it is quite possible that it should keep a woman sterile for a life-time. It would also account for the backache complained of; but when we come to consider the violent dysmenorrhœa also present, we find that it does not offer any satisfactory explanation of that. We shall, therefore, have to continue our examination further. We have certainly got hold of one key, but it seems that more than one is required for this case.

Proceeding, now, to introduce the uterine sound, I found that it was obstructed at the os internum, showing the existence of a stricture at that point. As the stenosis prevented the entrance of the sound altogether, I resorted to the smaller uterine probe, and presently succeeded in passing it over the obstruction into the cavity of the body. The moment I did so, however, the patient complained of the most extreme pain, and, in fact, the introduction of the instrument, under the circumstances, had very much the same effect that a dentist's probe would if knocked sharply against the exposed nerves and sensitive dentine of a carious tooth. The withdrawal of the uterine probe here was followed by some blood, which showed that the organ was in a state of intense congestion. I may also state that the uterus was larger than it should have been, the cavity measuring three inches instead of two and a half, which is quite remarkable in connection with the fact that she has never been pregnant. Here, then, we have the second key to the case.

But still, notwithstanding that we now have possession of the keys, it is a very difficult case. The patient has told us that she was perfectly well up to the time of her marriage, six years ago; but on questioning her a little more closely, I find that the dysmenorrhœa really commenced about two years before that time. The exact time of the beginning of her trouble does not matter; but from the present condition of affairs, I take it for granted that at some particular period, which is now too remote to learn much about, the patient did something which was the means of bringing on this uterine catarrh from which she is now suffering. While the uterus was in a state of engorgement, in consequence of the menstrual excitation, she, no doubt, exposed herself to cold; in all probability getting her feet wet. Like an ordinary cold in the head, for instance, this gave rise to a catarrhal condition, which, under the circumstances, naturally affected the uterus. In consequence of the inflammatory process thus set up, lymph was thrown out, and the stricture of the *os internum* finally resulted. Or, it is possible that the stricture was congenital, as is occasionally the case. At all events, we have two links in the chain of pathological evidence in this case. The first is this obstruction to the escape of menstrual blood from the uterus, and the second is the inflammation of the lining mucous membrane of the cervix and body of the uterus. In this way the dysmenorrhœa, the leucorrhœa, and all the symptoms, are accounted for in the most satisfactory manner.

What, then, is the prognosis here? If you should say there is an active inflammation going on, and I am going to apply active remedies, such as strong caustics, to the interior of the uterus, I should feel very skeptical, indeed, about your ever curing the case. In my opinion, the first thing to be done is to overcome the stricture at the os internum, and thus give free exit to the menstrual blood, which now always gets dammed up behind it. Although blood of this character does not coagulate nearly so

readily as ordinary blood, it always does coagulate under the circumstances present in this case. So little blood can escape that a clot soon forms behind the stricture, and then the uterus is driven to such active contractions (to the intense suffering of the patient), that it is at last forced through the narrow passage. Then the process is repeated over and over again (the uterus swelling up, contracting violently, and forcing the clots out), until the menstrual period has come to an end. Such a process as this is a very frequent cause of inflammation of the mucous membrane of the uterus, and sterility is extremely likely to result from its consequences. In the present instance the seminal fluid is prevented from entering the uterus, not only by the plug of mucus hanging from its mouth, but, also, by the obstruction offered by the stricture at the *os internum*.

In the treatment, then, the very first step is to overcome this stricture which has existed so long; and without this is done, as I said before, I do not believe it is possible to cure the patient. The question then comes up, what method shall we employ for this purpose? There are two principal ways of accomplishing the result desired; the first being by dilatation, either gradual or rapid, and the second by incision. In regard to dilatation, I may say that some authorities at the present day advocate very strongly what is known as the "glove-stretching" method. The patient is first etherized, and then forcible dilatation is accomplished by means of an instrument which works exactly in the same manner as a glove stretcher. This, as it seems to me, is a very unsurgical procedure. When the "stretching" is made, you can hear the tissues tear, like moist chamois leather, and an amount of violence is done to the parts which would seem as though it must be followed by the most injurious consequences; yet, nevertheless, very admirable results have been reported from it by a number of observers. But still I must confess that I am afraid of the operation, and would rather perform the bloodiest ovariotomy than attempt it again. I have had some little experience with it, and have seen just enough of it to make me thoroughly dislike it. It is, in fact, about as brutal as tooth drawing, and there certainly can be no more brutal operation than that in surgery.

A neater, and in my opinion more efficient, method of accomplishing the same result is by the persevering use of uterine tents. One objection to it, however, is that it keeps the patient in bed a good deal, while it requires considerable time, and not a little patience on the part of the medical attendant.

But the method of overcoming the stricture which I consider altogether the simplest and the safest, is that by incision. In performing this I would warn you against employing any instrument which acts in such a manner that you cannot really tell what is being done by it; and would advise the use of simply an ordinary probe-pointed bistoury, which should first be carried beyond the seat of stricture, and then drawn from within outward, dividing it in the same manner that a urethrotome would, in the case of a stricture of the male urethra. But the division of the stricture is not all. If the treatment of it should stop here, it would be a complete failure. After the incision has been made, it is important that a glass plug or short stem pessary should be inserted in the cervical canal, and retained in position by means of a pessary in the vagina, until permanent dilatation of the os *internum* has been accomplished.

From this time free escape for the mucus would be permitted all the time, and free exit for the blood at the menstrual period. This would, no doubt, completely relieve the dysmenorrhœa, and accomplish not a little toward the cure of the patient; but you would still have the endometritis to treat (I cannot now go into the details of such treatment), to say nothing of the sterility. Still, under any circumstances, I would not promise the patient a complete cure; and especially in regard to the last point. In a considerable proportion of cases, however, impregnation does take place after such a course of treatment as I have indicated in this instance; and when pregnancy once occurs it seems to exert a very beneficial effect, in permanently restoring the uterus to its normal condition. I have devoted a considerable amount of time to this case, simply because, as I said, large numbers of just such patients will consult you in the future, and I want you to fully comprehend the difficulties which you will meet with in connection with them, as well as the best methods of overcoming them.

Case 2.—Large Uterine Fibroid.

The next patient is Eliza C., a native of England, forty years of age, and single.

How long have you been complaining? "For three years." Were you perfectly well up to three years ago? "No, I was not." But your present trouble commenced then? "Yes." In what way did you suffer before that time? "I lost a great deal too much blood at my monthly periods." Did you lose any between your periods also? "Yes, frequently." For how long did this state of affairs continue? "For about fourteen years." Now, what have you complained of during the last three years? "Principally pain in the bowels." Anything else? "Great trouble with my bladder." Do you have to pass your water very often? "Yes, very often, and I have a good deal of pain with it too." Is there anything else that gives you trouble? "No." You do not, then, lose too much blood at your monthly periods now? "No." Do you lose any between your periods now? "Only very seldom, and then but very little." Do you have much pain during your sickness? "Yes, a great deal." Do you have to go to bed at that time? "Yes, on account of the pain, and because I feel so very weak." How long do you have to remain in bed? "Three days."

You see how pale this patient is, gentlemen. It would seem that she does not lose too much blood at the present time; but she is evidently suffering from the effects of the hemorrhages which have troubled her during a long period of years in the past. She is very anæmic, and her pulse is also quick and small. The only other symptom of which she complains (besides those already noted) is headache, and when questioned

as to its locality she places her hand upon the temporal region; which would seem to indicate that it is neuralgic in character, and in all probability due to her anæmic condition.

Although naturally averse to an examination, the patient, after some little persuasion, consented to one, in the hope of being relieved from the symptoms which trouble her, and the first thing that I encountered, in attempting to introduce my finger into the vagina, was a hymen, which was so narrow that it was necessary to give the patient a considerable amount of pain before I could get past it. I know of one quite eminent physician in this city who holds the view that the hymen, whenever found, is pathological; but such an opinion I consider a gross libel upon the sex. At this clinic, I am happy to say, we meet with a very large number of hymens in unmarried women. Well, having slipped my finger beyond the hymen, I found the cervix so high up that it could with difficulty be reached, and on resorting to conjoined manipulation, I found that the uterus was enormously enlarged. Moreover, the moment that I passed it between the two hands, the patient complained of great pain. It was not difficult to see, however, that this was not the pain of inflammation, but was rather neuralgic in its character. I also ascertained the fact that the uterus was lying over upon the bladder, which at once explained all the difficulty of which the patient had complained in regard to her water.

Now, what has caused the increase in the size of the uterus? The first thing that occurred to me was that it was a fibroid tumor, but in order that this diagnosis should be established, it was, of course, an essential point to exclude utero-gestation, for the condition of the hymen, of itself, is certainly by no means sufficient to do this. The hymen may be absolutely perfect, and yet pregnancy exist, and a number of such cases, which are entirely well authenticated, are on record. But here there was plenty of other negative evidence in regard to this point. The uterus, instead of giving the characteristic sensation of pregnancy to the fingers on palpation, was hard, like a billiard ball, and, in addition, all the mammary, gastric, vaginal and cervical signs of the condition were lacking. Since utero-gestation is to be excluded, therefore, let us inquire whether a fibroid of the uterus would offer us a satisfactory explanation of the symptoms which have formerly and now trouble the patient.

The more that we examine into the case, the more completely will we be convinced that a fibroid is the source of all the difficulty here. These tumors, as you know, constitute one of the most frequent of all the causes of both menorrhagia and metrorrhagia, and it is undoubtedly such a growth about the uterus that has given rise to the uterine hemorrhages from which this woman suffered for fourteen years. That during the last three years these have been gradually diminishing is, in all probability, due to the fact that she is now approaching the menopause. As to the trouble in regard to the bladder, we have already seen in exactly what manner that is produced.

We come now to consider the question, where is this fibroid located? On account of the pain which the examination gave the patient, I have been unable on the present occasion to determine whether it is sub-mucous, interstitial, or sub-peritoneal in character. The point could easily be ascertained, however, if she were to be etherized, the sound passed, and a more thorough exploration made. But so far as it would have any practical bearing upon the case, this would be an entirely unnecessary procedure; for even if I found out positively that the fibroid was in the cavity of the uterus, I would not think of actively interfering in such a case as this. It is always a dangerous operation to dilate the cervix and remove a uterine fibroid. Many operators have no doubt accomplished it with impunity; but a large number of others, just as careful in their manipulations, have encountered the most serious consequences in attempting it; so that we should always beware of trusting too exclusively to our own individual experiences. Most of you are probably not aware, from personal experience, what it is to have a bullet enter your bodies, but you are all sufficiently convinced, from that of others, that it is a dangerous matter. Out of a very large number of cases, I have myself lost two patients after the operation, in which it was absolutely necessary to remove uterine fibroids, on account of the extreme disturbance to which they were giving rise. In each instance septicæmia originated from the effect produced by the tent employed to dilate the cervix. You may, perhaps, do it twenty times in succession and not lose a patient or meet with any difficulty whatever, but yet there is always a certain amount of danger connected with the procedure. If the fibroid comes down within reach, however, it is a very different and a much simpler matter. Then you have only to seize it with the volsellum forceps, and enucleate it by meaus of the serrated scoop, which I have before shown you.

But, in the present instance, the indication, undoubtedly, is merely to let the patient alone, and I should certainly consider it criminal surgery to attempt to remove this fibroid, which is now doing her so little harm. Especially should such a course be reprehended, in view of the fact that she is really getting well of herself, because approaching that time of life when fibroids almost invariably cease to give rise to any trouble whatever. During the past four years, however, she has lost a very large amount of blood, and, consequently, she is still suffering from the effects of it, and needs building up. Then, as you know, there are certain drugs which have the effect of diminishing the blood supply of the uterus, and by far the most active of these is ergot. I should, therefore, recommend that this patient should take twenty drops of Squibb's fluid extract of ergot every night and morning, and that this medication should be kept up for an indefinite period; possibly for five years to come. There is no danger, as some might apprehend, of producing gangrene of the part by the long-continued use of ergot, for there is no instance on record, so far as I know, of the drug's giving rise to this effect when administered in medicinal doses. It is altogether possible that the ergot may cause such contractions

of the uterus that, in time, the fibroid may be forced out into the vagina, if it is of the submucous variety.

As to the prognosis of this case, I am confident that the patient will never die of any trouble connected with this tumor, unless it should be in consequence of the unwise interference of some practitioner who does not appreciate the real state of affairs here. I have so often known the use of sponge-tents to be followed by the most serious consequences that I have been much surprised to see in a late medical journal a long article from the pen of an eminent European authority, whose purpose is to show that they are not at all dangerous; and I cannot but believe that it is calculated to do a great deal of mischief. In the same way, about every five years, some one comes out in the journals with the important discovery that uterine injections are perfectly harmless; but if you should happen to question the writer about the matter some little time afterward, you would almost invariably find that he had given the method up, although he might not, perhaps, explain very fully the reasons which had induced him to do so. So, too, in regard to the use of intra-uterine stem pessaries. Very enthusiastic advocates of the instrument from time to time arise, but after a while you find that they all give it up. Yet I myself am in the habit of using both sponge-tents and stem-pessaries in my practice; although fully recognizing, as I do, the dangers connected with their use, I do not resort to them unless I believe it to be absolutely unavoidable. It is just three ago since I put in my last intra-uterine stem, and this is the first day that I can consider the patient out of danger of a fatal result from its effects. Then, why use such agents at all, you may ask. Simply because in certain instances the object desired can be accomplished in no other way. The simple passage of a catheter has been known, in occasional cases, to produce urethral fever, lymphangitis and death; yet no one would think of abandoning the use of the catheter in general, in consequence of such an accident. In the same way we continue to use sponge-tents. But we are fully aware that serious consequences may possibly result; and I would not have you deluded into the idea that they are by any means free from danger. I do not suppose a fortnight ever passes without my introducing at least one sponge-tent; but I make it a rule always to inform the friends of the patient (not the patient herself) that the procedure is attended with a certain amount of risk. This I consider to be the duty of the medical attendant in every instance; for if he should announce that the introduction of a tent was a trifling operation, not in the least dangerous, and in four or five days afterward the patient should die from peritonitis in consequence of it, he would certainly be placed in a very unenviable position. Such an unfortunate occurrence can always be avoided if you recognize the dangers incident to such a method of treatment; and if you consult any gynæcologist of experience and frankness, he will tell you that there is danger in putting anything whatever into the cavity of the uterus. Even cotton which has been saturated with thymol or carbolic acid may give rise to the most serious consequences, if allowed to remain in the uterus for twenty-four hours; and the same is true of the mere passing of the uterine sound.

Case 3.—Ovarian Epilepsy.

I should like to dwell at considerable length upon the next case, gentlemen, but the lateness of the hour will compel me to be very brief in my remarks in regard to it. The patient's name is Delia K.; she was born in Ireland, and is twenty-six years old, and single. She has been sent here by Dr. Frederick T. Brown, of this city, and as she herself is unconscious during the phenomena which constitute the chief feature of her trouble, it will not be worth while to attempt to get the history from her own statements. Dr. Brown, in the note which he sends with her, states that she has had epileptic fits for the last thirteen years, or ever since she was thirteen years old. Two of these occur with quite marked regularity every month; one coming on at the beginning, and the other at the termination of her menstrual period. The object with which the patient comes to us to-day, therefore, is to find out whether there is any trouble connected with the organs concerned in menstruation sufficient to account for, or, at least, influence, her disease.

You are all, no doubt, aware that the affection called epilepsy is one about which we know almost nothing. Up to twenty years ago the profession was in absolute ignorance concerning it, but since that time one physiologist, Brown-Séquard, has done more than all observers who preceded him together, to throw light on the subject. Among other things that he discovered in connection with the disease was, that there was usually some focus of irritation (which might be itself very trifling), which really gave rise to the convulsive seizures. Thus, in the guinea pig, which is peculiarly liable to epilepsy, he found that by simply causing an irritation of the ear, for instance, fits would result; and, moreover, that when the animal recovered from the injury, the epilepsy also became well. In the human subject, a cicatrix upon some part of the body, or the results of some injury about the head, may be the exciting cause, and instances are on record in which the removal by trephining of a spicula of bone pressing upon the brain has permanently cured patients who had long been suffering from the disease. In some women ovulation seems to afford an irritation sufficient to give rise to epileptic fits. Although a strictly physiological, it is also a most extraordinary, process, when we come to think of it (involving, as it does, an actual rupture of the ovary); and accordingly, we find it to frequently have a profound effect upon the whole economy. Not a few women are always a little insane during the menstrual period, and many of them feel and act differently at that time from what they do at any other. In the lower animals, also, a complete change of disposition not infrequently characterizes the period of œstruation, and I have known a mare which was ordinarily as gentle as possible to become vicious and almost unmanageable at this time. In some women, as in this instance, the convulsions occur at the be-

ginning and also at the end of this period; while in others they continue all through it.

When I made a physical examination here, I could discover no trace of uterine disease whatever; but the moment that I began to press upon one of the ovaries, in making conjoined manipulation, the patient became affected in the most remarkable manner, and as I continued the pressure, I thought she was about to have a violent convulsive seizure. If I had kept it up any longer, it is altogether probable that she would actually have had one; and she afterward told me that she experienced the same feelings that she always does just before the fit comes on her, at the beginning of her monthly sickness.

Next comes up the subject of treatment. In all cases of epilepsy the indication is to discover and remove the source of irritation, if possible. Having done this, if the disease does not get well, our main reliance must be upon the bromides, as Brown-Séquard has taught us. Where these fail in a case like this one before us, it has of late years been proposed by Dr. Battey, of Georgia, to remove the ovaries altogether. This operation has now actually been performed in quite a number of instances, and in a pretty large proportion of them the patients have died. Dr. Engelmann, of St. Louis, has recently reported, with great frankness, three cases, all of which proved fatal. Personally, I have performed the operation twice. The first time it was in the case of a young lady who was subject to epileptiform seizures, which, however, did not amount to epilepsy. She was engaged at the time, and she afterward married (the matter having been fully explained to and concurred in beforehand by her future husband). This was eight years ago, and the lady is still troubled with the convulsive seizures just as before, notwithstanding the removal of both ovaries. The second time that I performed the operation was in the case of a lady who always became actually insane at the time of her monthly periods. Once she had attempted suicide, and twice to take the lives of her children. She died of acute peritonitis, following upon the removal of the ovaries. The mind of the profession is not as yet fully made up in regard to the operation; but I am firmly convinced that, like the use of sponge tents, it is justifiable in some cases. I believe that it has been established that in about one-half of the cases which recover the epilepsy is cured in consequence of the operation.

Medical Societies.

BRITISH MEDICAL ASSOCIATION.

The forty-seventh annual meeting of this Association was held at Cork, Ireland, commencing Aug. 5th, in the Examination Hall of the Queen's College.

FIRST DAY.

Dr. Falconer, of Bath, occupied the chair, and there was a very large attendance, the spacious hall being completely filled. The galleries were tenanted by a large number of students.

The General Secretary of the Association read the minutes of the last annual extraordinary general meeting held at Bath, and when they had been confirmed

The President (who was very warmly received) addressed the meeting as follows: "Gentlemen, the period of my presidency is rapidly drawing to a close, and I must soon give up this chair to the President elect, Dr. O'Connor, of Cork. Perhaps, however, you will allow me a few moments before I quit the chair, while I lightly touch on some of the more salient occurrences which have taken place in our Association during the past year. It is probable that you will hear some of them in the annual report, but still, at the same time, I think them worthy of some passing notice from the retiring President." The President went on to say that the total number of members was 7800, and briefly reviewed several of the undertakings in which the Society was interested.

After the close of his discourse, Dr. O'Connor took the chair, and was introduced by Dr. Sullivan, President of Queen's College. A vote of thanks to Dr. Falconer was unanimously passed.

Dr. Falconer having briefly acknowledged, in suitable terms,

Dr. Carpenter said he wished to read out a list of a number of distinguished foreigners who were present. These gentlemen were not members of the Association, but he wished to announce that during their stay they would be honorary members of the Association. Their names were as follows:—

Prof. Charcot, Prof. Ball, Dr. Gallard, Dr. Bonnafont, Dr. Lowenberg and Dr. Gueneau de Mussy, of Paris; Dr. Herschberg, Dr. Weber-Liel, and Dr. Martin, of Berlin; Dr. Giacinto Pacchiotti, of Turin; Dr. Cordes, of Geneva; Dr. Lewis A. Sayre, President of the American Medical Association; Dr. Beard, Dr. Seguin, Dr. Gray and Dr. Hodgins, of New York; Dr. Yandell, of Louisville; Dr. Laurence Turnbull and Dr. Da Costa, of Philadelphia, and Dr. A. B. Palmer, of the University of Michigan.

The President, Dr. O'Connor, then delivered his address. Having referred to the city of Cork, and the social and moral condition of its inhabitants, he proceeded:—

"When several thousand men, many of them the most distinguished and honored in their profession for genius and learning, are banded together for one common object, we will readily assume that object to be large, comprehensive and benevolent; and what purpose of greater magnitude can occupy the human mind or stir the human heart than the effort to lighten the burden of sickness and misery, and to defer the inevitable death in which we all have a common inheritance. In forwarding this work, we follow our instincts as men, obey our duty as physicians, and receive a divine sanction as Christians. It can, then, be well understood how so many, leaving their homes, crossing the seas or ocean, have come here to unite in this common brotherhood of benevolence. I only hope the success of this meeting, by increasing our knowledge, and diffusing throughout the entire medical community sound principles to guide our practice, may be the reward of their sacrifices. The briefest

reference to the subjects which have been undergoing investigation by members of this Association since its last meeting (embracing the most important and abstruse problems in medicine) would show that they are imbued with the same disinterested zeal and filled with the same lofty ambition as those to whom I have referred. They do not, however, constitute a large section of this Association, and would not of any similar assembly. *Non omnia possumus omnes*—we cannot all do all things, but every one can do something toward the common object. For the practical man—the every day working physician—there is presented the important duty of collecting facts, from which the man of genius will derive general principles, and thus assist in bridging over the large space which divides physiology and pathology from practical medicine. To make a good syllogism, with physiology and pathology as major and minor premises, and the treatment of disease as the conclusion, remains still the difficulty to remove which all our energies are directed. Theories founded on imperfect generalization cannot be adopted in medicine with as little injury as in other sciences. It is of no consequence to the student of optics whether the modulatory theory of light be true or false, or to the astronomer whether the Copernican system is capable of mathematical demonstration, but it is of great moment to the physician as to whether alcohol is a food or merely a stimulant, whether it is entirely or in part, or not at all, consumed in the body; and still, contradictory statements of this kind have been propounded for the last twenty years, in succession, each professedly founded on experiments. In this instance, as in many others, error passes, by a species of exosmose, to the general public, who adopt the views more agreeable to the senses, believing alcohol to be indispensable for the cure of all diseases, and for sustaining bodily health and mental energy. Happily, the timely declaration of 260 of the most eminent London physicians—which might be printed in letters of gold—placed the question on its true basis, stating that 'while unable to abandon the use of alcohol in *some* diseases, no medical practitioner should prescribe it without a sense of grave responsibility, and with as much care as any powerful drug.' This and several other instances show that although practical men should bow to the declarations of science, they should hesitate before accepting unfinished generalizations, which a fresh experiment or a newly ascertained fact might destroy. Even deductions derived from experiments on animals, to test effects of medicines on the living organisms, though of great value, must be received with a certain amount of caution—justified by the fact that certain deadly poisons for man are nutritive food to some animals; that zymotic diseases are not intercommunicable between men and animals, or rarely so; and that even age and idiosyncracies modify the effects of medicines, so as to make it uncertain as to what may be the effect of a given medicine in one case by seeing its effects in another. Add to this the unnatural condition in which the animal experimented on is placed. How modestly, and at the same time philosophically, does Dr. Rutherford express himself on this subject. After 'fourteen hundred hours of hard labor,' spent in his investigation, he says, 'the experiment on the healthy liver of the dog, on the normal and abnormal human liver, are three sets of experiments, closely related, but still distinct. The facts derived from any one of the three cannot be substituted for either of the other two. Each set of facts has its own proper place, and must be kept there.' And then he advises the clinical observer to test in his practice the deductions derived from experiments on animals. We can thus see that in the deliberations which will take place in the sectional meetings, there is a place for the purely practical as well as the scientific man. Their views test and are tested by each other. Rationalism enlightens empiricism, and enlightened empiricism is a check, a drag chain, on hasty theorizing, from which medicine suffered so much injury through its whole history. Much as science has accomplished in establishing the physiological action of many medicines previously used empirically, the practical physician must still, in most cases, be guided by the results of the combined experience of wise men, free from egotism, vanity, self-interest, or other passions which cloud the judgment and prejudice its conclusions—while always hoping for and striving after a full knowledge of the relation between the medicine and its physiological effects. There are many diseases entirely under the control of medicines, others only partially and indirectly, and a third class, zymotic diseases, in which we can only apply our treatment to the cure of symptoms, and regulation of functions, leaving to nature the task of bringing the disease to a favorable issue. I believe that all attempts to cut short these diseases are fruitless or injurious. In the early part of this century a different opinion prevailed, and attempts were made to arrest fever by strong purgatives and bleeding. This violent treatment was soon discontinued, but I cannot help thinking that there are again signs of a return to the old heroic treatment, when in a work of the highest repute I find it recommended to begin treatment of typhoid fever with four doses of calomel, of eight grains each, six cold baths in twenty-four hours, 27 to 45 grains of quinine, to be given frequently in the course of the disease, and 22 grains of digitalis as an ordinary dose. We walk in darkness with a slow and cautious step, but here, where we are utterly ignorant of the processes by which the poison is eliminated from the system, we are recommended to give medicines which would test the constitution of one in perfect health. This treatment, though recommended by deservedly high authority, has not as yet found favor in this country, where confidence in the curative powers of nature in this class of disease still prevails. When we see the care with which each bodily organ is protected, and the wisdom with which their functions are regulated for the preservation of life, we cannot believe that Creative power which arranged these things so wisely would send the finished work adrift to combat with destructive forces, without prearrangement for reparation in case of injury, internal as well as external, in fever as well as in fractured limbs, or union by the first intention. The physiology of health is not more wonderful

than what may be called the physiology of disease, by which disturbed functions are restored to their normal condition. It is not a humiliating office for the physician to study the means by which nature accomplishes her ends, and as far as his knowledge permits, to imitate her. I know the assertion of a '*vis medicatrix naturæ*' is now nearly obsolete, and equally so the seeking of primary causes for vital phenomena. These old fashioned ideas have been extinguished by modern philosophy, which asserts that all organization and its operations are the result of blind chance, without a mind to fashion or to guide them. The physician, with his opportunities for observation, must be blind indeed, who does not see beyond this darkness a clear light, showing him that all nature has been conceived and formed in beauty and order, the result of a divine purpose, directed by divine benevolence." * * *

After the address, Dr. Carpenter presented the annual report of the Council of the Association, showing that it was in a flourishing condition.

The report was discussed and accepted, and the meeting adjourned.

SECOND DAY.

At eleven o'clock the second general meeting of members of this Association was held in the Examination Hall of the Queen's College.

The President (Dr. O'Connor) occupied the chair, and the hall was well filled with medical gentlemen. Mrs. Garret Anderson, the only lady member of the Association, was in attendance.

Nominations for Council were then read by Dr. Carpenter.

Dr. Carpenter next proposed that Cambridge be the place of meeting for the Association in 1880, and that Professor Humphrey be appointed President.

The resolution was passed.

Dr. Alfred Hudson, Regius Professor of Physic in the University of Dublin, then read an address on medicine. He reviewed the earlier history of medical progress, and dwelt at length on the work done by the celebrated French physician, Lænnec. The lecturer alluded to the discovery of auscultation by Auenbrugger, and mentioned that the idea of the stethoscope was suggested to Lænnec by seeing some children playing in Paris—holding their ears at the opposite ends of a beam of wood, and conveying from one to the other the sound produced by tapping on one end. Lænnec was not slow in turning what he observed to practical account, and the result was the discovery of the stethoscope. He was afterward enabled by means of this instrument to arrive at correct ideas with regard to the nature of the severest chest diseases, as well as disease of the heart. Dr. Hudson proceeded to describe in detail the views held by Lænnec, and contrasted them with those of more modern observers, especially Niemeyer, whose views on pulmonary consumption were at variance with those of Lænnec, and in which no one, however, could deny there was a great deal of truth. The address closed with a touching reference to the great loss recently sustained by the Association and by the profession, in the death of Dr. Charles Murchison, whose life work presented some analogies to that of Lænnec. Like him, Murchison had left an imperishable memorial in his classical work on the continued fevers of Great Britain.

Thanks were returned to the writer, and after some general discussion the proceedings terminated.

THIRD DAY.

The third general meeting was held in the Examination Hall of the College.

Dr. D. C. O'Connor, President, occupied the chair, and there was a large attendance of members.

The first business was the reading of the report of the Medical Reform Committee.

Dr. Edward Waters, of Chester, Chairman of the Committee, read the report, which stated that it is with no slight feeling of satisfaction that the Medical Reform Committee have to report to the members that the period seems to be at last approaching when a satisfactory termination to the long continued and consistent efforts of the Association in regard to medical reform may reasonably be anticipated. The original programme of medical reform, promulgated by the Association nearly half a century ago, has never been departed from.

The speaker described at length the various efforts at reform in Great Britain, and mentioned the progress made during the last year, which he spoke of as very satisfactory.

William S. Savory, F.R.S., Surgeon to and Lecturer on Surgery at St. Bartholomew's Hospital, at eleven o'clock, delivered an address in Surgery, on the prevention of blood poisoning in the practice of surgery. He said, in the course of his remarks, after speaking of the great dangers arising from blood poisoning, and the means he had taken to prevent it in cases under his care, "For the rest, I shall take the liberty of trying your patience for a few moments by describing somewhat more in detail the practice I follow, because I believe that results equal to the best hitherto obtained may be thus reached. Well, then, taking a case—say of amputation through the thigh, or of excision of the breast—I should treat the wound in the way following: Having arrested all hemorrhage, using most probably the carbolized catgut ligature, and having gently removed any particles of blood clot that may have lodged on the surface, employing only clean water or sponges just rinsed out of it, I should, without any further interference with the surface of the wound, bring the edges together, adapting these as nicely as possible with silver wire sutures. I should not in this way attempt to close the wound completely, but I should leave spaces between the sutures, perhaps from one to two inches long. Then, over the course of the wound and for some distance on each side of it, I should place a layer of folded lint, which had been previously well soaked in olive or almond oil, containing one part in about fifty of carbolic acid. Over this again I should place two or more layers of dry lint, either with or without cotton wool; so arranging this as, by gentle and equable pressure, to secure without any violence, as far as practicable, the accurate

adaptation of the surfaces of the wound throughout, avoiding thus any considerable cavity in the interior. I should secure all this by strapping or bandaging, or both, so adjusting these that they may be hereafter removed with the least disturbance. I should place the patient and the wound in the most comfortable position possible, having especial care to the fact that fluids, as they form, may flow outward. Thus, for instance, after excision of the breast, I have, for some time past, placed the patient, not on her back, but on the opposite side, so as to make the inner angle of the wound the most dependent part of it. I am convinced that this assists greatly in promoting speedy and satisfactory repair. It is much better for fluid to escape at the inner than at the outer angle, and this more especially when the axilla has been disturbed by the removal of glands. The cellular tissue is so very much less abundant and less loose toward the sternum, that the chance of infiltration of it by fluid is very much less. As a rule, perhaps, I do not disturb this arrangement for forty-eight hours, although very often I change the dressing and inspect the wound after twenty-four. I am guided in this matter of time chiefly by the state of the patient; whether spare or full-bodied; his sense of local and general comfort, freedom from or complaint of pain; and the season or temperature. But whenever I am in any doubt I change the dressings. These, then, are removed with the utmost gentleness, and the state of the wound carefully inspected. Especially is attention directed to whether there is any tendency to the lodgment of fluid; whether that which forms can escape freely; whether there is much tension of the edges. I am bold enough to think that a surgeon who understands his business can tell, without any painful handling, whether the surfaces of the wound are fairly in contact, or whether there is any tendency to the accumulation of fluid separating them. But if any doubt arise on this important point, a perfectly clean probe or director, lightly applied to some portion of the wound, will solve it and secure ample vent; if at all necessary, I should not hesitate to remove one or two or more sutures. If the wound presented no other evidence than that of satisfactory repair, I should dress it as before, and proceed in this fashion, dressing and examining it daily or less frequently, according to circumstances. But if at the first dressing, or at any time afterward, the discharge became at all profuse, or the surfaces did not remain in contact, or there was much tension or a blush at the edges, I should forthwith substitute a bread-and-water poultice for the previous dressing, and probably continue to employ this until at least all the deeper portion of the wound had closed. When I dressed the wound, I should wash it, probably from the first, with tepid water, perhaps containing some permanganate of potash in the form of Condy's fluid, or other potent antiseptic of the least irritating kind. I should accomplish this, washing out, if I thought fit, portions or even the whole of the interior, by the use of a syringe, avoiding contact of sponges or other substances with the wound. I aim here at the utmost possible cleanliness, having at the same time due regard to the avoidance of any unnecessary disturbance, that the process of repair be not interrupted. And withal I endeavor, by means I need not indicate, to secure for my patient the most complete rest and pure air. With regard to the substitution of a poultice or water dressing, or some other form of application for the simple dressing used in the first instance, I think one can tell for the most part beforehand if they are likely to be required at all, or early in the management of the wound. In young persons in tolerably good health and spare, most wounds, when not worried, heal very directly. It is in those advanced in life, with flabby textures and much loose fat among them, that wounds give most trouble. These pour out fluid freely and are prone to flag, and while the process of repair is delayed, may fall into mischief in various ways. Now, I am sure you will allow that this mode of treating wounds in general, which I have thus slightly sketched, is characterized by its simplicity and the entire absence of all novelty; my purpose being to interfere in the least degree possible with the work of nature. Some years ago it would not be worth recording; and now, perhaps, it will excite surprise to find that any plan of treatment with so little in it is still adopted. Allow me yet to trouble you with a few comments. In the first place, at the time of the operation, or immediately after, you see, nothing is applied to the wound but water; as a rule, no antiseptic of any sort, provided the surface of the wound is healthy; because I believe that such healthy, natural surfaces are in the state best adapted to satisfactory repair; and that, as a rule, in proportion as they are changed by the application of foreign agents, so are the changes which initiate repair hampered or arrested.

The speaker went on to state his objection to drainage tubes, which he does not employ.

At the conclusion of his address a vote of thanks was passed.

On motion of Dr. Carpenter, the Association, through the President, presented a gold medal to Surgeon Major Reynolds, for bravery and energy in performing his duties in the Zulu war.

The meeting then adjourned.

Powdered Aloes as a Dressing for Wounds.

Seeing the advantage which is derived in veterinary practice from the dressing of wounds by powdered aloes, Dr. Millet states, in the *Gazette Hebdomadaire*, that he has employed it in a case of lacerated phalanges, and reports very favorably as to the benefits derived from it. He considers that it fulfills a double indication, acting as a cicatrisant and as a means of dressing by occlusion, for the powder becomes agglutinated under the influence even of the heat of the hand, and lines the wound with an impermeable layer which prevents the contact of air, assuaging the severe pain of the wound almost immediately. The dressing has also the advantage of being very simple and only requiring renewal at long intervals.

Sterility as the Result of the Operation for Stone.

In Dr. Parker's study of 131 cases of lithotomy, in the *Transactions* of the South Carolina Medical Association, he says, on the above point—

The relation which this operation bears to subsequent sterility is of great interest, for several reasons which readily suggest themselves, and it is a question by no means settled. It can only be done by a close observation of a large number of cases. That it does produce sterility, in the great majority of cases, is well known. It is also reasonable to suppose that one mode of operating is more likely to produce it than another. Yet surgeons are not agreed upon this point. It would be a great triumph in surgery to determine the exact cause of sterility, and to devise some plan which, while avoiding such an unfortunate and unhappy result, would not lessen the chances of recovery and relief from so painful and distressing an affection. Unfortunately the information afforded in the history of these cases will not assist us much in arriving at any conclusions on this point. The result of the operations bearing on sterility or non-sterility have only been mentioned in a few cases. I allude to this point more particularly, because Dr. T. T. Robertson, of Winnsboro', calls attention to two cases of sterility, one in his own practice, the other in one of Prof. E. Gedding's patients; and Dr. Ogier mentioned to me that the same had occurred to one of those he had operated on, and he believed that it was nearly always attended by this effect. One of Dr. Crook's and two of Dr. Bartlett Jones' were also sterile. Professor F. M. Robertson's patient has several children; so have the patients of Drs. Miles and Daring and one of Dr. Campbell's. These cases were all bilateral or lateral operations, and three of them with the same instrument, yet the result was very different. How are we to explain these different effects of the same operation with the same instrument upon separate persons?

On Introducing the Hand into the Rectum.

In the *Practitioner*, Dr. G. De Gorrequer Griffith recommends this procedure to allay post-partum hemorrhage, and to diagnose uterine diseases. Several cases of death from rupture of the rectum have been reported, referring to which he says—

It is quite true that the introduction of the hand into the rectum is a difficult operation, and attended with some danger, if the operator have a large hand, and be rough and hurried in his manipulations, thrusting and forcing the hand into the bowel, or attempting to do so, instead of gently, and with boring motion, working in the fingers folded together cone-shaped, and well larded, and then the hand narrowed as much as the operator possibly can. If there were malignant disease of the bowel, or organic stricture, then, indeed, if the operation were attempted, it would be difficult and most dangerous. But in such instances no man should be rash enough to attempt such a proceeding, and would, of course, by digital examination, first ascertain the state of the bowel. I can understand that in some cases, other than childbed, it would be especially difficult, if called upon to perform it without being able to have had the bowels cleared out, though such must be extremely rare, and dangerous to some, because of pain and shock, if anæsthetics could not be administered. But in post-partum patients it is not so difficult, because the bowels have been unloaded during the parturient efforts; their muscular coats are relaxed, as well as the sphincters, owing to the post-partum loss and hemorrhage, which call for such interference; and the necessity for inducing anæsthesia obviated because of the unconscious or semi-unconscious state of those patients in whom the operation is needed; and the introduction of the hand will, indeed, ofttimes be a judicious stimulus toward rousing the sinking energies.

It must be borne in mind that it is a last resort; and it will prove a very effectual one, I have no doubt; that the patient is *in extremis*; and, that there is only the choice between her dying of hemorrhage, and the performing of this operation.

Salicylic Acid in Rheumatism.

Twenty cases of this treatment are reported from the Massachusetts General Hospital, in the Boston *Medical and Surgical Journal*, with the following comments:—

In reviewing these cases the following facts are observed: In eight cases out of seventeen which were treated with salicylic acid, the duration of the disease from the beginning of the attack, without reference to length of treatment, was in the longest case twenty-six days, and in the shortest five days; the improvement being very marked from the beginning of the treatment. In four of these cases there were one or two slight exacerbations of pain relieved in from two to six days by small doses of the acid. Of the three patients who took the salicylate of soda only, even including the length of illness before entrance, the duration of the disease was less than twelve days in each case, the shortest time being two days. In the remaining nine cases, the duration of the disease was either six weeks and more, or was so masked by some complication that satisfactory results could not be obtained. In two of these cases there was very marked improvement after taking the acid; in one the treatment was discontinued on the second day, owing to wild delirium; in another pleurisy supervened, masking the symptoms; and in five the treatment met with varying success, the symptoms constantly recurring and showing little improvement from the use of the acid. The length of illness before entrance in these cases varied

from five days to three months. Out of seventeen patients who used salicylic acid, in five nausea and vomiting were produced; in eight, deafness and noises in the head; and in five, delirium, one being wild for thirty-six hours. Of the three who took salicylate of soda only, there was no gastric nor cerebral disturbance. In regard to the comparative merits of the treatment by salicylic acid and the salicylate of soda, a fair estimate cannot be made from these cases. In the three who were treated by the salicylate of soda the recovery was very rapid, but in no one of them was the attack of a very severe nature.

Judging from the foregoing cases, we are justified in coming to the following conclusion: that although salicylic acid is not a specific remedy for every case of rheumatism, yet in acute cases, if the treatment be begun within a few hours, or at most a few days, from the onset of the disease, and pushed vigorously, the most satisfactory results may be obtained. Care should be taken, moreover, not to omit the treatment immediately after the cessation of pain, but gradually to diminish the dose.

Second Attacks of Yellow Fever.

On the debated question whether persons can have a second attack of yellow fever, Dr. Simons writes, in his observations on the epidemic of 1878, in the *Transactions* of the South Carolina Medical Society—

There were a number of cases reported, and several deaths, among patients who had had fever in previous epidemics in Memphis, or elsewhere. While I am not prepared to deny the statement, as reported by physicians of repute, and for whose judgment I have a profound respect, yet in the history of all such cases that I had access to, the report of the first attack was incomplete. The facts elicited were that the patient had had some febrile disorder during the prevalence of yellow fever; was never very sick, and the physicians pronounced it yellow fever. During the prevalence of an epidemic, there is a system of generalization in the classifying of diseases, or they are spoken of as being impressed with the type of the prevailing epidemic. This difficulty I experienced in Charleston, during the widespread epidemic of 1871. Yellow fever existed without doubt, and also a large percentage of what was called "Ephemeral Fever," "Dengue," and by others, not willing to commit themselves to a decided opinion, "the prevailing fever." The mortality of that year was less than five per cent. In a report made at that time I classified my cases. There was undoubtedly the same epidemic influence that impressed them all, but I am doubtful as to future exemption from malignant yellow fever in those who had the hybrid forms of fever. But I do believe that one who has had a typical case of yellow fever will be exempt in future.

To substantiate this, I point to the fact that four physicians and fifty-four nurses left Charleston in August, and remained in Memphis and the surrounding infected region, exposed fully to the most malignant form of disease, undergoing the most arduous and exhausting duty, until November 1st. None of us had yellow fever, and all were well when ready to return home. The nurses comprised many foreigners, Germans, Italians, and Irish; the services of none were accepted for this duty, except those who had had the yellow fever. I think this number is large enough to draw a positive conclusion, as to exemption from second attacks.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——A vest-pocket arrangement for giving the doses of the most important drugs, according to the metric system, has been prepared by Dr. W. F. Whitney and Mr. F. H. Clark, and published by A. Williams & Co., Boston. Price 25 cents.

——The *Canada Medical and Surgical Journal* will in future be edited by Drs. George Ross and W. A. Molson. It will appear hereafter on the 15th instead of the 1st of the month. Another change announced is that the Louisville *Medical News* is hereafter to be styled the *Medical Age*.

——The sixth part of the *Atlas of Histology*, by Dr. Klein and Mr. Smith, is upon the structure of the spinal cord, nerve centers and brain substance. These important and difficult branches of histology are treated with great clearness, and the illustrations are most accurate and instructive. (Phila., J. B. Lippincott & Co.)

——The pamphlet of the Massanutten Mineral Springs Company claims that that water is "almost a specific" in a long list of diseases. Some little evidence offered seems to show that it is beneficial in the malarial cachexia, which may be owing to a trace of arsenic it is said to contain. The pamphlet is as worthless for information as such generally are. The Springs are near Harrisonburg, Va.

——In a reprint by Dr. John M. Keating, of this city, descriptive of a case of ulcerative endocarditis, with pyæmia, he gives strong grounds in favor of the opinion that primary abscess of the heart, or primary ulceration, if it proceed far enough, independent of general myocarditis, is occasionally found. He does not offer any explanation, except that it may be due to disease of the lymphatic channels or the glands.

——As opposed to the metric system, Dr. J. F. Baldwin, of Columbus, Ohio, has reprinted some remarks before the Ohio State Medical Society. We shall refer to them editorially at some future time. Suffice it at present to say that there are strong and sound reasons for *not* adopting the system at present in the United States. Many journals have gone too fast and too far in this matter.

BOOK NOTICES.

The Druggist's Handbook of Private Formulas. By John N. Nelson. Third Edition. Cleveland, Ohio, 1879. 8vo, pp. 338. Price $3.00.

For the use of druggists, Mr. Nelson has here collected a large number of formulas, such as are most frequently made up in apothecary stores. His sources of information are the Pharmacopœias, Dispensatories and trade journals most in authority at the present time. The formulas are classified under a "pharmaceutical department," a "perfumery department," proprietary medicines, miscellaneous formulas, and a number of "semi-officinal" formulas. In the form of an appendix, he adds a number of useful hints, such as the tests of essential oils, adulterations of spices, formulas for artificial wines and liquors, frigorific mixtures, mode of detecting mixed or rectified whisky, etc.

In the various formulas given for manufacturing artificial wines and liquors, it is gratifying to note that directly poisonous substances are not employed. The basis of the wines is cider and alcohol, sweetened, colored and flavored; of the liquors, alcohol diluted. In practice, however, the new and fiery distillate known as "high wines" is employed, rank with fusil oil, and frightfully heady.

The book is neatly printed and bound.

Guide to the Examination of Urine; with Medical Reference to the Diseases of the Urinary Apparatus. By K. B. Hoffman and R. Ultzmann. Translated from the second edition by F. Forcheimer, M.D., Professor at the Medical College of Ohio. Cincinnati, Peter G. Thomson, 1879. pp. 195. Price, cloth, $1.50; leather, $2.00.

In Germany this brief treatise has met with considerable success. The translator tells us that it has been nearly universally adopted by the German "high schools" (?). The authors begin with a description of the structure and functions of the urinary organs, which we think quite unnecessary, as every student learns this before he reaches the examination of urine. The physical characters, chemical constituents, and microscopy of the sediments then follow in the order noted, to which succeed a description of the simpler diseases of the organs, in a chapter on Diagnosis. This arrangement is not the most desirable, but it is the one generally adopted, more, we suspect, for the convenience of writers than for the accommodation of readers. In a work designed for clinical instruction, signs, symptoms and diagnosis should go together.

The book has no table of contents, and is not very well printed; nevertheless, the criticisms we have made upon it must not be construed as a condemnation of it; as it is a carefully written work, and accurately translated.

Transactions of the Medical and Chirurgical Faculty of the State of Maryland, 1879. pp. 196.

Transactions of the Medical Society of the State of Tennessee, 1879. pp. 213.

The original papers contained in the first of the above-mentioned reports are, "Remarks on a Case of Glaucoma," by Dr. J. A. White; "Facts in Connection with Squint," by Dr. J. J. Chisholm; "Yellow Fever," by Dr. T. B. Evans; "Cerebro-spinal Meningitis," by Dr. C. H. Ohr; "The Thermantidote," by Dr. H. P. C. Wilson; "Treatment of the Insane," by Dr. J. S. Conrad; "Dipsomania," by Dr. I. D. Thompson; "Progressive Paresis," by Dr. G. Liebman; the "Rubber Bandage," by Dr. J. E. Atkinson; "Salicylate of Sodium," by Dr. W. J. McDowell; and "On a Tumor of the Neck," by Dr. T. C. Maddox. We observe that not only was Dr. Van Bibber's paper refused (see REPORTER, current volume, page 122), but charges were preferred against him for allowing extracts from it to be published. This was very small business for the "Medico-chirurgical Faculty" to be engaged in.

The Tennessee *Transactions* contain several able papers on yellow fever, by Drs. Hope, Thornton and Wight. Their observations are original and careful. Dr. Thomas Lipscomb records an interesting case of ovariotomy, with successful result. Dr. J. W. Penn developes a new theory of malarial diseases, to wit: that their cause is "enervation, from privation of electricity, caused by the evaporation of *pure water*" (italics his). We pass to Dr. Atchison on the uses and abuses of alcohol. It were hard to find less tenable views than he advocates on the subject of man's physical degeneracy, on page 64. That a university professor should make such statements would seem incredible; but was it not from the university that he is attached to that a learned man was lately removed for believing in evolution? That explains Professor Atchison's obscurantism. There are several other original papers, and a long necrological report by Dr. Wise, on the physicians who died of yellow fever in Memphis last year.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Half-Yearly Compendium of Med. Science,	**2.50**
Reporter and Compendium, - - -	**7.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**8.25**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

PHILADELPHIA, PA.

COFFEE TAVERNS AND TEMPERANCE SALOONS.

The effort to prevent the sale of intoxicants by passing prohibitory enactments has been almost given up in this country. We hear much less about it than ten or twenty years ago. Where it has been tried, it has usually proved unsuccessful; the endeavor to make it a political "issue," on any large scale, has completely failed; and the opinion is gaining ground that it is better to convince the public that the use of the stronger alcoholics as beverages is, on the whole, hurtful, than to attempt to force on them, by law, such an opinion, when they don't believe it.

Meantime, other and more rational endeavors are being carried out to remove the temptation to drink alcohol. It is being recognized that men crave and will have some stimulant, some analeptic, some nervine tonic, or narcotic, and that if they can as easily and pleasantly imbibe one which is of moderate power, they will not run after those more potent and more virulent.

In countries where the Mohammedan and Buddhist religions prevail, both of which forbid, as one of their most stringent injunctions to the pious, the use of fermented liquors or intoxicating *drinks* of any kind, they whip the devil around the bush by smoking opium and chewing hasheesh. The Siberian savage stupefies himself with a poisonous fungus, or by swallowing tobacco; and the coca and maguey were prized for the same purpose by the red Indian before Columbus saw the shores of the New World.

Hence, it is rational to supply this universal craving, and it is wise to supply it with some substance which will have the minimum of ill effects. For this purpose there has been, of late years, both in this country and England, a great increase in coffee houses, cocoa taverns and holly tree inns; and their success has been decisive. At the opening of one in England, the other day, the Right Hon. J. H. WALPOLE remarked that many excellent persons in that country were of opinion that the vice of drunkenness might be effectually dealt with by governmental coercion and prohibitory restrictions; but in his own mind he was confident that no attempt on the part of a government to remedy the evil could ever succeed. What Government could do in the matter it had already done, and any further legislation would only have the effect of setting the people in opposition to the law. They wanted some place of meeting where they could enjoy social intercourse without the temptation to indulge in excessive drinking, and this necessity these coffee taverns amply provided. In this last-mentioned respect we do not think the coffee houses in this country are equal to those in England. If there is one in Philadelphia where one can enter, have a seat, a table, the evening paper and a cup of coffee, all for five cents, as he can in any of a thousand beer saloons, we don't know it.

Enough attention has not been given to introducing, and preparing in agreeable form, the various stimulating and soothing vegetable infusions which may take the place of the cup which inebriates. Coffee and tea are by no means the only ones which are to be found. Cocoa and chocolate, as prepared in the United States, are

usually flat and nasty; but as in Mexico and Central America, strengthening and delicious. Paraguay tea, or maté, is said to be agreeable to the taste, and must be largely consumed, as the annual crop on the government lands in Paraguay is officially reported to be worth $200,000. It is a species of *Ilex*, and another species, *Ilex cassine*, grows in our Southern States, and has been used as a domestic beverage. Both contain between one and two per cent. of caffein.

As a mild stimulant, the coca (*Erythroxylon coca*) of Peru ought to be largely cultivated. The German traveler, Dr. Von Tschudi, found an infusion of it most invigorating after great toil. Very little of it finds its way to foreign nations. According to the official statement of the government of Peru only fifteen hundred weight (15 quintales) were exported in 1878. Were the demand greater, no doubt more would be cultivated.

Pure coffee should be on sale at such taverns; but the public should be induced, by their lower price to prefer some of its modified forms, "coffee-surrogates," as they are called. In Europe, chicory is one of the most important of these; and as it is imported into the United States at the rate of nearly *four million pounds* a year, our people must drink considerable more of it than they are aware of. It makes, mixed with coffee, a healthful and excellent beverage, and to our own palate more agreeable than the pure coffee.

The *Chemiker Zeitung* mentions a process recently patented in Germany for a similar substance. Wheat is boiled by steam heat, and well washed, to remove all impurities. A proportion of 3 per cent. of bicarbonate of soda is then added, the mixture is dried, roasted and ground, and is then ready for sale.

Many of the vegetable bitters could be made into palatable and refreshing beverages, acting sufficiently as nervines to remove the sense of fatigue.

Where such drinks could be had, together with newspapers, seats, games and other amenities, people would very willingly pass their hours of relaxation, and not want intoxicants.

NEW REVELATIONS IN SANITARY SCIENCE.

It is highly gratifying to the philosophic mind to be relieved from groundless fears; and after the hullabaloo that has been raised by heedless sanitarians about noxious effluvia, foul drinking water, offensive sewer gas, and the exhalations of decaying animal and vegetable matter, it would surely be a relief to all to discover that this alarming talk has little foundation in fact, and that we can sleep in a room impregnated with the air from a sewer, and drink the fluid from that same channel, without risk to our health. Here were certainly a matter for congratulation.

Several recent writers strive to carry us to this conclusion.

From one of them we have already quoted in this journal—Dr. George Hamilton, of this city. In the last volume of the *Transactions* of the College of Physicians of Philadelphia, he has a paper on the relation of sewer gas to typhoid fever, an abstract of which we gave at the time it was read (see Reporter, volume xl, page 384). He endeavors to disprove the assertion that sewer gas is the most potent and common cause of typhoid fever, in this or any city; indeed, he considers any such view "utterly untenable," "in direct antagonism with facts;" and, in fact, argues that sewer gas has nothing to do with typhoid. Nor is he willing to credit the opinion that the effluvia arising from decaying vegetable matters is a source of the disease.

When it is considered that the typhoid condition is closely akin to typhoid fever, that it often can hardly be distinguished from it, and must have the same or a closely allied cause, the exclusion of sewer gas and decaying organic matter from its etiology assumes a wide and most important interest for the surgeon as well as the physician.

Diphtheria and scarlet fever have been also attributed to these same agencies; but several writers have recently decried this with great vehemence. They point to the intense severity of these maladies in secluded farm houses, in well drained mountain hamlets, in windy and dry up-

land villages. It is claimed that diphtheria is often more fatal in such localities than in the most densely populated blocks of down town, New York; hence, that this malignancy has nothing to do either with foul air or impure gases.

Much stress has been laid on the importance of pure drinking water, especially that it should be free from organic, particularly decaying matter. But here comes Dr. Rudolf Emmerich, one of those redoubtable Germans who are always found ready to sacrifice themselves on the altar of science. He determined to put this matter to the test, and as he was, like Cæsar, not afraid to

> "Drink from the gilded pool
> That beasts would cough at,"

he selected two of the dirtiest open ditches in Munich, and made their undiluted contents his daily beverage, to the amount of a quart or more. He first examined this water chemically and microscopically. It was to the eye dirty, and to the nose foul smelling, and that to such a degree that it was difficult at first to avoid involuntary vomiting after taking it. It contained fragments of garbage, dirty rags, hairs of men and beasts, particles of feces, etc., as the trench was the general receptacle of privies, dirt carts, dead cats, and the like.

For the first day or two after beginning the use of this water, Dr. Emmerich suffered from headache, loss of appetite, catarrh of the bowels, coated tongue, and other symptoms of a light gastritis. In three days' time all these symptoms disappeared, and for a month, during which he continued to drink the water, he was as well as ever. Next, he persuaded two convalescents in the hospital to try it. One had been suffering from constipation, headache, loss of appetite and muscular pains; after a few days' use of the ditch water, *he decidedly improved.* The second had been long a victim to dilatation of the stomach and dyspepsia. He was not the least injured by the free consumption of the putrid fluid. Finally, about a month after the doctor had ceased his experiments, he happened to be attacked with a sharp gastro-enteritis. He rejoiced at such an opportunity of testing his ditch water, and therefore, without using any remedies, he began to drink it freely. In a few days he was well!

From these experiences (which will be found in the *Wien. Med. Blatter*, No. 6, 1879), Dr. Emmerich concludes that "the use of the most foul and putrid drinking water produces no injurious result on the system in health; and even existing affections of the intestinal canal are not in the least aggravated by it."

What have the sanitarians to say to these facts and arguments? Is our dread of uncleanliness, after all, a mere figment of the imagination? Shall we give up sewer traps, and close drains, and water filters, as useless expenses?

For ourselves, we confess we are far from satisfied that they are needless; and we still lean to the opinion that pure air and water, a clean skin and a calm conscience are all efficient measures in preserving health and prolonging life.

Notes and Comments.

Cataphasia.

This is the name applied by Dr. Renzi, of Genoa, to an affection of the speech, the characteristic symptom of which consists in the patient being obliged to repeat over and over again the same words; he having either pronounced these words spontaneously or in answer to a question. Thus, a patient being asked how long he has been ill, repeats fourteen years, fourteen years, fourteen years, and so on, five or six, or even more, times. Or, he will give a clear and correct answer to the question, and go on repeating this answer indefinitely. There is usually hereditary, nervous weakness, and often a history of drunkenness in one or both parents.

Artificial Alkaloids.

Synthetic chemistry is nearing every day the perfection which will enable it to produce the alkaloids, instead of deriving them from the crude product. The latest conquest in this field has been the formation of artificial atropia. This has been successfully effected by Ladenburg. He could discover no difference in physiological effect between this artificial and the purest natural atropia.

May we not expect an artificial quinia soon, which will equal the natural one in therapeutic powers? Nothing is more probable.

A Biographical Dictionary of Contemporary American Physicians.

It is announced that the work which was published last year by Mr. Charles Robson, of this city, under the title "The Physicians and Surgeons of the United States," is to be republished, with corrections and additions, under the title which heads this notice.

The work will contain biographical sketches of about 3000 contemporary regular physicians of the United States, prepared from materials in most instances furnished by themselves, and hence entirely trustworthy. The effort will be made to embrace all who have visibly contributed to the advancement of medical science. Instead of costing ten dollars, half bound, which was the price of the first edition, the new edition, revised and enlarged, will be furnished, bound in full leather, for *six dollars;* or in cloth, for *five dollars.* As the text will cover about 900 large octavo double-column pages, and will be on fine tinted paper, this will be seen to be an unusually low figure. Nevertheless, all who send in their names as subscribers to the work *before* October 1st will receive it when issued, delivered free of postage, at a discount of *ten per cent.* off these rates. As the edition will be limited, all who wish the volume will do well to forward their order (to be paid for when the book is ready for delivery, about Dec. 1st,) and obtain this advantage, and be certain of securing a copy. Communications should be addressed to the editor of this journal.

Ignorance of Veterinary Medicine.

We have been gratified by the reproduction of our editorial on Veterinary Medicine (Reporter, Aug. 9), by several journals, both medical and agricultural. A number of letters have been written us containing further inquiries on the subject, and illustrating the need of a more scientific study of the subject. One of these, from a physician in Vermont, says—

"I have practiced medicine in this village, which is surrounded by a dairy country, two years, and all the cattle that have died from disease, that I have heard of, and there has been a number, have died with 'horn ail;' at least, such has been the diagnosis made by our resident cow doctors, and most cases have been treated as such by injecting a decoction of red pepper and vinegar through a hole bored in the horn, and putting salt in an incision made in the end of the tail."

Such barbarous treatment is worthy of the darkest period of the dark ages. What is called "horn ail" is nothing but the anæmia of cattle (see Dr. Tellor's *Diseases of Live Stock*, page 289). There is evident need for the Veterinary Department of the University.

Vaginal Lavements for Vomiting of Pregnancy.

At a meeting of the Norfolk (Mass.) Medical Society, reported in the Boston *Medical and Surgical Journal*, Dr. Greene, of Dorchester, advocated the use of warm vaginal lavements for many cases of obstinate vomiting of pregnancy. He also spoke of a case where this expedient, as well as a variety of other measures, had failed to procure more than very transient relief. There was anteflexed cervix and a very rigid, impenetrable os. At the patient's own proposal, trial was finally made of vaginal injections of warm olive oil. These afforded relief, and during four or five weeks next following a fair measure of comfort was secured only by the regular use, two or three times daily, of such injections—the patient maintaining, for an hour or two after each, the dorsal decubitus necessary for effective lubrication of the os and cervix.

Treatment of Chronic Urticaria.

In a lecture on urticaria (*Gaz. des Hôp.*, June 19) Dr. Guibout observes that although in ordinary cases its treatment is very simple, and merely hygienic, when it becomes chronic and dependent upon permanent dyspeptic derangement medicinal agents are required. In this case, according to the particular indications, we should have recourse to emetics, purgatives, or stimuli, among which he prefers strychnia, given in the following form:—

℞. Distilled water, 120
Sulphate of strychnia 2
Syrup of mint 50 M.

A tablespoonful to be given before each of the three principal meals.

Alkaline and gaseous mineral waters, such as those of Vals or Vichy, are also very advantageously employed as a means of rendering digestion more easy and more rapid.

The Poison of Indian Corn.

In Italy a great deal of Indian corn is eaten in a spoiled, partly fermented condition, and is believed to give rise to the disease known as *pellagra* and other maladies. Italian chemists have detected in this fermented corn strongly poisonous products, isolated by them after fermenting perfectly healthy maize. Dr. Cortez and Prof.

Husemann's recent investigations confirm this view, but indicate that the principles were not isolated in a pure state, and that they have a varying influence on the nervous system, some prepared during the hot season proving as poisonous as strychnia, while others, obtained in colder weather, produced narcosis and paralysis, frequently accompanied by all the symptoms of nicotia poisoning.

Correspondence.

Physicians as Sellers of Drugs.

Ed. Med. and Surg. Reporter:—

I have read with much pleasure your remarks under the caption of "How some Dirty Shillings are Made by the Profession," and while concurring in most of what you have therein stated, it struck me that you had drawn the line rather sharply in respect to the practice of dispensing medicines by the physician in his own office. To my mind the practice is not only perfectly justifiable in every way, but is further supported by the precedent of long use by large numbers of honest and capable practitioners, who learned it from their predecessors. Among those who practice dispensing their own medicines, there has never come under my observation an instance where concealment was attempted, or considered advisable. In country districts it often becomes absolutely necessary for physicians to carry medicines with them, but in cities, where the population is denser, and physicians more numerous, it pays some person or persons to establish depots for the supply of drugs, etc., and thus obviate the necessity for physicians carrying a private stock. Druggists understand this point full well, and they also understand that theirs is a business venture entirely, and that physicians are not bound, either in honor or equity, to patronize them, but if they do so, it is for their own convenience. Were it not for physicians' prescriptions, very many druggists could not subsist at all, and they know it, therefore they make extraordinary efforts to divert the patronage of physicians to their particular stores, whereas, if it were irregular for the physician to dispense his own medicines, they would dictate instead of soliciting. In view of the foregoing, it seems to me that the *right* of physicians to dispense is undeniable, provided they so choose. What others may think upon this point would gratify me to learn, in case you consider these remarks worthy of publication.

Newark, N. J. Ernest M. Lyon, M.D.

[The context of our remarks plainly limited the criticism referred to to districts where drug stores are convenient, and further, to "dispensing and selling medicines." That physicians should give along with their advice the drugs they recommend is often necessary and proper; whether they should "dispense and sell medicines," *i.e.*, put up pharmaceutical preparations, and vend and trade in them, is the question. We are very decidedly of the opinion that such action is improper. Yet we know of apparently reputable physicians in this city who, in a private way, ply the old dodge—"advice gratis; no charge except for the medicine." Dare any of them come forward and defend it? The Reporter is open for them.—Ed. Reporter.]

Carbolic Acid in External Hemorrhoids.

Ed. Med. and Surg. Reporter:—

Having recently, in several of our prominent journals, seen the *declared inutility* of carbolic hypodermic injections in *external* hemorrhoids, and being a short time time since tempted to put that opinion to the test, I herewith detail my experience.

July 9th, 1879, I was summoned to the bedside of Mr. C., whom I found suffering intensely from a large external hemmorrhoidal tumor, which, by reason of a recent attack of diarrhœa, was accompanied with a prolapsed rectum. With the usual manipulations I immediately reduced the prolapsus, leaving "in situ" a hard, somewhat lobulated and spheroidal tumor, 1½ inches in its long, and ¾ inch in its short diameter, and protruding about half an inch beyond the level of the surrounding integument. Inquiry revealed the fact that this tumor had occupied its present quarters for twelve years, gradually getting larger, frequently the source of intense agony, and at all times the source of great discomfort.

A brief talk gaining my patient's consent to an operation for the removal of his tormentor, I quickly made preparations, and with a hypodermic syringe, charged with ♏ xx Squibb's sat. sol. phenol, I introduced the needle of my syringe in the long diameter of the tumor, and as near its base as possible, pushing it until its point impinged, without piercing, the opposite side. I then slowly withdrew it, discharging the contents of the syringe, until nearly reaching the point of entrance. I repeated the same manipulation in the same direction, in a line parallel, and distant about half an inch from the first injection. Again introducing the instrument in the shorter diameter of the tumor, I repeated the above manipulations twice in that direction. Finally, introducing the instrument in a vertical direction, in four different points, and about midway between the intersections of the longitudinal injections, I discharged the balance of the acid into the tumor. Considering that I had saturated the tumor sufficiently with the acid to ensure its destruction, I anointed it well with vaseline, applied a poultice, and enjoined rest in a recumbent posture for a few days, prescribing an aperient to keep the bowels soluble. No anodyne was required, as after the first introduction of the instrument the pain was only trifling.

July 12th, I visited my patient; found him very comfortable and able to be up about the house. Examination of the hemorrhoid revealed as perfect a sphacelated tumor as I ever saw, and even more *thorough* than could be produced with

a ligature. The discharge being somewhat fetid, I prescribed carbolated vaseline to be applied freely, and the poultice continued until the slough separated, which it did on the 15th, or on the 6th day after the operation, and while my patient was at *work* at his trade (tinsmith), which he had resumed on the 14th. No further difficulty was experienced in the case; a healthy granulating surface was left after the slough separated, which had perfectly healed by the 27th, with entire freedom from all pain and soreness on defecation.

I give this case thus, in (perhaps prolix) detail, for reasons given at the outset. I, at least, am perfectly satisfied that carbolic injections are *perfectly efficient* and safe for removal of *external*, as well as internal, piles, and infinitely prefer it to either knife, ligature or any other caustic method. P. M. SENDERLING, M.D.

Jersey City, N. J.

Persulphate of Iron in Hæmoptysis.

ED. MED. AND SURG. REPORTER:—

I shall be glad to have you find room for the following case: M. L., age thirty-eight, farmer, thick set, broad chest, rather robust in appearance, has been spitting small quantities of blood occasionally, for the past twelve months. In childhood he had frequent attacks of epistaxis. He has no cough nor pain, and the plexiometer does not discover any disease in the lungs. Until recently the hæmoptysis has been so slight, and so easily checked with salt or alum, that it gave him no uneasiness, but within the last month or two it is more abundant and frequent, sometimes twice a day. The usual tickling in the throat which precedes it was experienced while talking with me, and in a few seconds the blood appeared, at first slight, then, very soon, by mouthfuls. Salt and alum were promptly and frequently given, but without effect; also, gallic acid and ice. All these having failed, I gave him one grain of persulphate of iron in a wineglass of water; this checked it *at once;* nothing could have acted quicker. Fearing a return, however, I directed him to repeat the dose three times a day for several days, and remain quiet. This was three weeks ago, and he has had no return. J. DABNEY PALMER, M.D.

Monticello, Fla.

The Tongue in Typhoid Fever.

ED. MED. AND SURG. REPORTER:—

In Vol. XLI, No. 5, I find a short, but able, article on the appearance of the tongue, by Dr. Henning, not in any particular disease, but its appearance as indicative of acidity or alkalinity of the system. Most practitioners will admit the statement that with a broad, pallid, furred tongue we have an acid condition of the primæ viæ, and that in all of such cases we have an acid breath, and in half of them nausea and vomiting of an acid material or matter. In the deep red tongue we seldom have nausea or vomiting, or even an acid breath, and no doubt an alkaline state of the fluids of the body.

I have just treated a case of typhoid fever, in which the tongue was of a bright red through the whole of the disease. I kept my patient on 30 drops of nitro-muriatic acid every three hours, from the first time I saw the case. On the eighteenth day improvement began. While the same patient, one year before, was similarly affected, and the treatment lacked the acid; the disease lasted twenty-eight days before improvement began. A. T. LEVICK, M.D.

Woodville, Mo.

NEWS AND MISCELLANY.

American Academy of Medicine.

The fourth annual meeting of the American Academy of Medicine will be held in the rooms of the New York Academy of Medicine, 12 West Thirty-first Street, New York, commencing Tuesday, September 16th, at three o'clock P.M.

The following programme has been determined upon:—

Tuesday afternoon: organization, election of members, unfinished business, general business. Tuesday evening, at 8 o'clock: address by the President, Lewis H. Steiner, A.M., M.D., of Frederick, Maryland, on "The Preparatory Education Most Needed by the Medical Student." Wednesday, 10 A.M.: general business; paper by Elisha Harris, A.M., M.D., of New York, on "Hygiene and the Higher Researches of Sciene;" election of officers; introduction of President elect.

RICHARD J. DUNGLISON, A.M., M.D.,
Secretary.

Comments on Quinine Legislation.

The New York *Times*, of recent date, says:—

"Legislative action in respect to quinine, as such things generally are, was hasty and precipitate. Without expatiating on the possible good which may be derived by the community from the abolition of the duty, it may be insisted upon that the question of quinine was by no means well understood in Washington. Any manufactured article derived from a crude material which pays a duty is more or less complex in it character. One-half of the wise law makers of the last Congress could not tell quinine from Glauber salts. We doubt not the leaders believed, as a direct result of their hasty legislation, quinine would be reduced in price and made better in quality, and that the measure would at once be popular with the people. When both of these propositions fail and quinine goes up, as it has, and the quality of the imported article grows poorer, as it will, the mistake will be made plain, even to the ordinary Congressman. Quinine pure is cheap at four dollars per ounce when compared with a spurious article at one-fourth the price. Every medical man in the United States knows that the article of quinine made in this country was pure and always reliable, while the practitioner is constantly deceived by imported drugs, and the sick made to suffer."

We do not blame the legislators in Washington for their stupid action so much as the medical

men that urged them to it, avoiding free discussion of the subject as much as possible, and descending to the arts of politicians in their endeavors at diplomacy.

Ex-Surgeon General Hammond Exonerated.

WASHINGTON, Aug. 27.—The Secretary of War, under direction of the President, has reviewed the proceedings and findings of the court-martial of January 16th 1864, by which Surgeon General Hammond was dismissed the service, and recommends that the findings and sentences be annulled and set aside, and that, in accordance with the authority conferred by the Act of March 15th, 1878, the name of William A. Hammond be placed on the retired list of the army as Surgeon General, without, however, back, present or future pay allowance, as Dr. Hammond distinctly disclaimed any desire for such.

The recommendation of the Secretary of War has been approved by the President.

The Mackinnon Pen.

Indefinite in number are the various "fountain pens" we have tried, and the only one which has met our wants or answered the statements of the salesmen is the "Mackinnon Pen." It has had a full test in our office, and we have found it all that is claimed for it. It holds ink enough to write three or four pages of foolscap, does not leak, flows freely, does not wear at the point for a long time, and is portable and handsome. Physicians should prefer it to a pencil for writing prescriptions, as it prevents alterations, etc. It is cheap, for the price, and we recommend it. Those who would provide themselves with such an article should address the agent, who advertises on advertising page 179 of this number.

Mortality in the Tropics.

The average annual mortality of Pará, Brazil, is about 60 per 1000; in St. Kitts, W. I., the annual mortality rises as high, some years, as 74 per 1000. Throughout the West Indies the autumn is the most unhealthy season, and dysentery and yellow fever the most fatal epidemics. A correspondent of the *Southern Clinic* attributes the short lives of Europeans in the West Indies chiefly to exposure to cold and dampness, and to alcoholic beverages.

Pregnancy at Eight Years of Age.

A remarkable instance of early pregnancy is reported by Dr. Molitor, in the *Gaz. des Hôpitaux*. No. 57. A well-developed girl commenced to menstruate when four years old; at eight and a half years of age she was delivered of an embryo, together with a hydatid mole. At that time she was large for her years, the breasts developed, the pudenda covered with dark hair. She acknowledged to have had frequent connection with a man of thirty-two years six months previously.

Items.

—In surgical instruments, and mathematical and astronomical apparatus, says the *Revue Industrielle*, French workmanship has deteriorated so much that the attention of the Government has been directed to the subject.

—The cholera in Japan, at last accounts, continues virulent, but there have been signs of abatement within the last month. Thus far there have been 45,000 cases and 25,000 deaths. The Government displays unflagging energy in confronting and checking the disease. It is said to have been introduced by a German vessel, which disregarded the quarantine regulations.

—A young lady, who was one of the most enthusiastic of the converts at a camp meeting at Urbana, Ohio, last month, fell into a trance while praying. Her friends believed that her condition was the result of a special blessing, and would not permit a physician to do anything for her. She lay unconscious several days, and finally died, of spinal meningitis.

—The London *Athenæum* remarks that this year witnesses the first successes of women in the arts, science and medical examinations of London University, the competition now taking place on a footing of perfect equality, since the London Medical School for Women has its lectures recognized as qualifying, and also the attendance of women on the practice of the Royal Free Hospital is recognized. Four have passed the Prelim. M.B., London, just over, in the first class and none in the second class.

MARRIAGES.

BERLET—WALTER.—On the 6th ult., by the Rev. John Thompson, at the residence of the bride, James F. Berlet, M.D., and Margarite E. Walter, all of Philadelphia.

CLEVELAND—CONOVER.—On the 14th ult., at the First Unitarian Church, by the Rev. W. H. Furness, Samuel M. Cleveland, M.D., and Julia H., daughter of the late William H. Conover, of Freehold, N. J.

McCORD—HARRY.—On the 16th ult., at Sunnyside, Chester county, Pa., by the Rev. George G. Field, Benjamin McCord, of Philadelphia, and Lydia, daughter of Dr. S. H. Harry.

SIMONTON—CAMPBELL.—At St. Paul, Minn., August 11th, by Rev. W. Simonton, Dr. Thomas D. Simonton and Mrs. Emma M. Campbell, both of St. Paul.

STRAWN—FOLKROD.—On the evening of the 12th ult., by the Rev. A. J. Rowland, Dr. J. Strawn and Lucy Packer Folkrod, both of Philadelphia.

DEATHS.

HULL.—In New York City, on Friday August 22d, Mary Delafield, wife of Dr. Joseph J. Hull, and daughter of Cornelius DuBois.

MITCHELL.—In this city, on August 16th, 1879, S. B. Wylie Mitchell, M.D.

MORGAN.—At Suffield, Conn, on Friday, August 15th, Dr. Edwin D. Morgan, son of the Hon. E. D. Morgan.

NAGLE.—In this city, on the 15th ult., Dr. George L. Nagle, in his 75th year.

POTTER.—At Fitzwatertown, Montgomery county, Pa., on the 12th ult., Harry Augustin Potter, son of Dr. Robert E. and Charlotte F. Potter, aged one year.

WOLCOTT.—In this city, on the 26th ultimo, Dr. Charles Resa Wolcott, in the 63d year of his age.

TAMAR INDIEN,

A laxative, refreshing, and medicated Fruit Lozenge, agreeable to take, and never causing irritation. Its physiological action assures the immediate relief and effectual cure of

CONSTIPATION, CEREBRAL CONGESTION, HEADACHE, INDIGESTION, BILE, HEMORRHOIDS, etc., etc., by augmenting the peristaltic movement of the intestines, without producing undue secretion of the liquids. Unlike pills and the usual purgatives, it does not predispose to intestinal sluggishness, and the same dose always produces the same effect, that is to say, never needs increasing. These properties render "Tamar" invaluable to the weak and debilitated, and especially to ladies previous and subsequent to their accouchement. It is recommended by the most eminent Physicians of Paris; notably Drs. BELIN and TARDIEU, who prescribe it constantly for the above complaints, and with most marked success.

Prepared by **E. GRILLON,** Pharmacien de lère classe, 27 Rue Rambuteau, Paris. To be had of all respectable Chemists throughout the world.

PEPTODYN.

The New Digestive is a combination of the whole of the Digestive Secretions—Pepsine, Pancreatine, Diastase, etc.,

Forming an invaluable remedy in the treatment of all forms of Dyspepsia, and diseases arising from imperfect nutrition.

N. B.—*The success of this Remedy has led to several imitations of it,* which consist largely of Milk Sugar, and, as compared with Peptodyn, are of little or no real value as digestive agents.

SAVORY & MOORE, 143 New Bond Street, London.

PARIS, 1867. Prize Medal.

1868. Silver Medal.

1872. Gold Medal.

1873, VIENNA. Medal of Merit.

BOUDAULT'S PEPSINE

IN POWDER, also WINE, ELIXIR, SYRUP, PILLS, AND LOZENGES OF PEPSINE.

Since the introduction of Pepsine by Boudault in 1854, **BOUDAULT'S PEPSINE HAS BEEN, AND IS STILL CONSIDERED, THE MOST RELIABLE,** as is attested by the awards it has received at the Exhibitions of 1867, 1868, 1872, 1873, and in 1876 at the Centennial Exposition in Philadelphia.

IT IS THE ONLY PEPSINE USED IN THE PARIS HOSPITALS.

Careful tests will enable any one to satisfy himself that **BOUDAULT'S PEPSINE HAS A DIGESTIVE POWER AT LEAST DOUBLE** that of the best Pepsines in the market, and that it is really the cheapest.

It is Sold in 1 ounce, 8 ounce, and 16 ounce Bottles.

Beware of so-called French Pepsines bearing fictitious names, and prescribe Boudault's only.

BLANCARD'S PILLS

OF UNCHANGEABLE IODIDE OF IRON.

Blancard's Pills of Iodide of Iron are so scrupulously prepared, and so well made, that none other have acquired a so well deserved favor among physicians and pharmaceutists. Each pill, containing one grain of proto-iodide of iron, is covered with finely pulverized iron, and covered with balsam of tolu. Dose, two to six pills a day. The genuine have a *reactive silver seal* attached to the lower part of the cork, and a green label on the wrapper, bearing the fac-simile of the signature of

Blancard

Pharmacien, No. 40 Rue Bonaparte, Paris.

without which none are genuine.

BEWARE OF IMITATIONS.

E. FOUCERA & CO., Agents,

NEW YORK.

NEW REMEDIES.

RECENTLY INTRODUCED BY US.

RHUS AROMATICA.

Highly recommended in the treatment of diabetes and other diseases of the genito-urinary organs, viz.: Hematuria, enuresis (in both old and young), uterine hemorrhage, and as a local application in leucorrhea; also in atonic diarrhœa and dysentery, and more especially summer diseases of children.

See article by Dr. McClanahan, in the April number of *New Preparations*.

We offer this new remedy in the form of a fluid extract from the fresh bark of the root.

FOLIA CAROBÆ.

JACARANDA PROCERA (SPRENGEL). This new drug, from Brazil, is now attracting the attention of the profession in Germany, as a valuable and effective anti-syphilitic. It is said to possess alterative, diuretic, sudorific and tonic properties, to a marked degree, especially in the latter particular. Hence its application to the treatment of syphilis in all its forms.

The Carobæ may be continued advantageously with Iodide Potassium in cases distinguished by pains in the limbs. It is indicated in the cure of old syphilitic ulcers, to which it may be applied topically.

CASCARA SAGRADA.

RHAMNUS PURSHIANA. This is the bark of a tree indigenous to northern California and Oregon, known botanically as the Rhamnus Purshiana. It has long been used on the Pacific Coast, among the Indians and old Spanish residents, as a remedy for habitual constipation and other disorders of the alimentary canal. Many physicians write to us that they must have the Cascara *at any price*, as it has proved invaluable in their practice.

We cannot too strongly caution physicians and druggists to specify "P., D. & CO.'S," if they desire a preparation of the *true* drug, Rhamnus Purshiana.

COTO BARK.

The tree from which this bark is derived is a native of Brazil and Bolivia, though as yet we *cannot locate it botanically*. Coto Bark was first tested clinically by Prof Gietl, of Munich (Germany), who considered it a specific for diarrhœa in its various forms. Dr. Riecker, of Stuttgart, concurred in this. Prof. Baetz, of Tokio, Japan, in the *Centralblatt*, recommends it for malignant cholera. In Bolivia it is used for diarrhœa, colic, and neuralgic toothache, and externally in rheumatism and gout. It has been also employed in the sweating of phthisis, and typhus, catarrhal diarrhœa, gastric catarrh, pneumonia, uterine colic, acute articular rheumatism, cholera, cholera morbus, dysentery, night sweats, etc.

FIVE FLOWERED GENTIAN.

GENTIANA QUINQUEFLORA. Among the many substitutes for quinine this plant is one of the most valuable. In many cases where quinine and other antiperiodics have proved futile, this remedy has been found very efficacious. In combination with hydrastis, it has been found an excellent tonic in depraved conditions of the digestive apparatus, increasing the biliary secretions and acting as a stimulant to the excretory organs. In fevers, in combination with gelsemium, and in derangement of the biliary organs, in conjunction with leptandrin and podophyllin, it seems to increase the action of those agents.

GRINDELIA ROBUSTA.

This remedy has been successfully employed in asthma, bronchial difficulties, iritis, vaginitis, and other diseases of the mucous surfaces. In combination with Yerba Santa it has also been found specially efficacious in bronchial affections. It is well known that many of the varieties of this family bear so close a resemblance to each other that it is difficult to distinguish between them, and the Squarrosa and other varieties are hence often unwittingly substituted for the Robusta. Our own supply is gathered for us under the direction of a competent botanist, and is known to be genuine.

DESCRIPTIVE CIRCULARS.

We shall be happy to furnish upon application descriptive circulars giving the botanical history and therapeutical application of New Remedies recently introduced by us. We will also send, if desired, our price list, giving names and prices of nearly two thousand articles manufactured by us.

☞ *Send stamp for Price List and Circulars described above.*

PARKE, DAVIS & CO.,

Always specify Parke, Davis & Co.'s. **DETROIT, MICH.**

Our goods can be procured of Messrs. W. D. ELLIOT & Co., Philadelphia; LEHN & FINK and WALTER ADAMS, New York; SMITH, DOOLITTLE & SMITH, Boston; and of druggists generally throughout the West.

SOLUBLE

Pills and Granules.

UNEQUALED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

1. The best materials are used in their manufacture.
2. No article required by a formula is omitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.

Our list of Pills and Granules embraces those made according to the formulæ of the U. S. Pharmacopœia; also most of those in common use among the profession.

Trade supplied in Philadelphia by

A CASE OF INVAGINATION OF THE LARGE INTESTINE—RECOVERY.

Read before the Northern Medical Society of Philadelphia,

BY W. M. WELCH, M.D.,

Of Philadelphia.

Robert P., an infant, aged 7 months, previously healthy, having been somewhat restless and fretful during Friday evening, May 17th, 1878, was seized about midnight with violent pain in the abdomen, and about one hour later with vomiting. On Saturday morning (18th) I found the child suffering from great pain, which was somewhat paroxysmal. There was also vomiting; fever, but not very high; face pale; countenance sunken, and indicative of great distress. There had been this morning a discharge from the bowels, consisting of mucus markedly tinged with blood. I ordered a small dose of castor oil, with a little laudanum, but the stomach did not retain it. In the evening warm water enemata were freely administered, the child being held at the time in a position by which the head and shoulders constituted the most dependent part of the body. With the object of quieting the pain, opium was ordered, in repeated doses.

19th. Pain and vomiting continue; has had a good deal of tenesmus. Since yesterday morning has several times passed mucus, mixed with blood. The infant is very much exhausted, and presents a deathly aspect. Warm water enemata were again freely used; and opium in the form of the deodorized tincture continued.

20th. Although maintained in a half comatose condition by the free use of opium, yet the pains recur paroxysmally, and the vomiting is renewed almost immediately after nursing. There is still an occasional discharge from the bowels, of mucus, tinged with blood. I tried this morning inflation of the intestines with air, but without success.

21st. The pains and the irritability of the stomach continue, though they are less aggravating than formerly. This afternoon had a small fecal passage, which was very offensive and dark in color.

22d. The stomach is less irritable to-day; retains the breast milk, also a little brandy, milk and water. Had a small fecal passage last night, and another this forenoon.

23d. Has had increase of pain since yesterday. Opium administered more freely.

24th. The paroxysms of pain are intense, and are attended by straining and bearing-down efforts. Had this morning another small fecal passage.

25th. The violent tenesmic and bearing-down pains continue. Has had two or three small and offensive fecal passages. The deodorized tincture of opium is still administered freely.

26th. The pains continue to be of the same character. Passed a little fecal matter this morning.

27th. Pains not so severe since twelve o'clock, midnight. Has passed no fecal matter, but has had several watery discharges, containing mucus and traces of blood. Vomiting set in again during last night, and the patient is very much prostrated, has a feeble pulse, great thirst, and a peculiarly anxious and sunken expression of the face. On introducing my finger into the rectum I discover nothing abnormal.

28th. The pain has abated considerably, and vomiting has occurred only a few times since yesterday. The discharges from the bowels continue watery and muculent, and contain only very little fecal matter. The child sleeps the greater part of the time, though the quantity of opium now used is much less than formerly. Takes nourishment (breast milk) quite frequently; also brandy and water.

29th. Is quite comfortable, suffering from pain only when the bowels are moved; has had three or four tolerably free fecal evacuations; vomited quite freely last evening, but not since; nurses freely; has required only two or three two-drop doses of laudanum since yesterday.

30th. Condition about the same as yesterday.

31st. Has had a little increase of pain since last evening; several fecal evacuations and no vomiting. The general appearance of the child has somewhat improved.

June 1st and 2d. Continues in about the same condition; the pains still come and go.

3d. Has had some very severe pain since last evening, and it has been accompanied by very great straining and bearing down efforts. There has been a great deal of rattling of wind in the intestines. Has had several evacuations from the bowels, some of them fecal, and others watery and muculent. The only nourishment the child is allowed to take is breast milk, and this it continues to take freely.

9th. Has been quite comfortable during the last six days, suffering only very little pain, if any. Has had three or four evacuations from the bowels each day, and some of them have been almost natural in appearance. The child is weak and very much emaciated, though he feeds well, and is at times inclined to be playful. The opium has been continued, though in smaller doses, and less frequently repeated.

10th. Child more restless this morning, and seems less disposed to take nourishment, though he does not appear to have much pain. The discharges from the bowels are largely composed of mucus.

11th. There has been no passage from the bowels during the last twenty-four hours, and vomiting has occurred two or three times. There has also been some return of pain. Opium increased.

12th. Has rested tolerably well since yesterday, the pains not being very great and the vomiting having ceased. Takes nourishment more freely; has had two or three movements from the bowels, of the same character as heretofore. There is in the intestines an enormous amount of wind-rattling.

15th. Very little change in the condition of the patient. The use of opium having been suspended for a day or two, the child is now uneasy and fretful, though he does not appear to suffer from very much pain. Takes plenty of nourishment, and a little pepsin is given after feeding.

25th. During the last ten days the general condition of the patient has remained unchanged. Although the pain has not been at all severe, yet frequent straining and bearing-down efforts have been noticed. This morning, after one of these efforts, a portion of the bowel, about three inches in length, was found protruding from the anus. At first sight it was thought that possibly this was simply prolapsus ani, but on introducing my finger alongside of the mass into the rectum, which I could do, I found that this gut, or the lower part of it, at least, was not at all prolapsed. I then introduced the mass within the rectum and pushed it up as far as my finger could reach, but it did not disappear. Warm water, by injection, was then freely used, with the child in the position previously mentioned, and opium, which had been discontinued for some time, was renewed.

30th. During the last five days straining has been a very prominent symptom, and prolapsus of the intestine has occurred nearly every day. The portion of the bowel now protruding is much greater than at first. The evacuations contain some fecal matter, a good deal of mucus, and sometimes a little blood. Again, warm water, by injection, was tried, in vain, to remedy the difficulty. To relieve the pain and straining, and to act as an astringent to the parts, opium and tannin suppositories were tried, but opium (deodorized tincture) by the mouth proves more satisfactory. In order to guard against the prolapsus, a compress is worn over the anus.

July 24th. Since the last record was made the patient's condition has not improved. The invaginated bowel may be felt at any time within the rectum, and very frequently is forced through the relaxed sphincter, in spite of the compress, and made to protrude from the anus to an enormous extent; indeed, as much as ten inches of the bowel has been seen protruding. In appearance it is very much congested, being of a deep red color, or slightly purplish, and when handled stains the hands with blood. It is also very much corrugated or puckered, and, in shape, presents an obtuse angle. The child has by this time grown excessively weak, and is greatly emaciated. In this condition he was to-day sent to the "Children's Seashore House," Atlantic City, in charge of Dr. Wm. H. Bennett.

September 4th. The child was brought home to-day, in a state of perfect health. Dr. Bennett informs me that the general condition of the child remained unchanged for about ten days after admission to the Seashore House. During this time the tenesmus, straining and bearing-down pains continued, and the bowel protruded from the anus several times, and almost always to a very great extent. Dr. Bennett's treatment consisted in replacing the mass and applying a pad to the anus, and another to the left iliac region. He kept the child the greater part of the time under the influence of opium, at first using it in the form of suppositories, but afterward preferring morphia by the mouth, as the suppositories seemed to produce tenesmus and straining. "Other than this," Dr. Bennett says, "the treatment was simply tonic, and I am thoroughly convinced that it was the improvement in the child's general health which led to the permanent cure."

The mother of the child, who is a very intelligent woman, sends me the following statement: "Early on the morning of the 2d of August the bowel came down further than it had ever been, and discharged more blood and matter (mucus) than it had previously done, the discharge continuing all through the day; but after that time there never was the slightest bearing down. During that week the child cut the four upper teeth, took food greedily, besides nursing, and the motions of the bowels become natural. He regained strength daily, and was quite well on our leaving the Seashore House, the first week in September."

Remarks.—Invagination of the small intestines is believed to rarely constitute disease in children under one year of age. Although those accustomed to make post-mortem examinations of infants have frequently found invagination in the jejunum and ileum, yet in all such instances death has resulted from some other disease, and wholly independent of any symptom of disorder of the bowels during the lifetime of the patient. It is, therefore, believed that this is a simple form of invagination, being produced and restored again without any suffering on the part of the infant; or else, that it frequently occurs during the act of dissolution. In children over two years of age fatal cases of this form of the disease have occurred, though not very frequently.

The two forms of invagination which constitute the vast majority of cases in children are, first, that in which the ileum passes through the ileo-cæcal valve, inverting and drawing down with it the cæcum and colon; and, second, that in which the cæcum is primarily inverted, and descends into the colon, inverting the latter, and drawing after it the ileum. A few cases of invagination of the colon alone are found on record. The above case is believed to be an example of that form of the disease.

The diagnosis of invagination in infants is usually not very difficult. The disease is indicated by obstinate constipation, vomiting, paroxysmal pains, tenesmus, straining, scanty passages of mucus or blood, or a mixture of both, and sometimes by the presence of the invaginated bowel in the rectum. But to make a differential diagnosis between the different forms of the complaint is often a matter of very great difficulty. In either of the two common forms of the disease already referred to, if the inverted intestine should descend through the whole length of the colon and rectum, and protrude from the anus, the gut would most likely become strangulated and impervious. Because, therefore, in the above case the gut did not become strangulated, but remained more or less pervious from the beginning to the end, except, perhaps, during the first three days of the attack, is one reason why I believe the disease to have been located in the large intestine.

In infants, invagination of the intestines, other than the simple form referred to, commonly proves fatal. But while death is the common result, yet there are two modes worth considering, by which life is sometimes preserved. One is reduction of the incarcerated bowel, which is followed by immediate relief. When the colon is the seat of the disease, there can be no doubt, I think, that reduction sometimes takes place through the unaided vermicular movements of the intestine. The foregoing case is certainly an example of recovery by this mode. Reduction, also, is sometimes brought about by mechanical means; such as the employment of water by injection, and air by inflation. Although both of these agents were employed in my case, and failed, yet I must confess that while the enemata were freely used, the inflation of the intestines with air was, perhaps, not as thoroughly done as it should have been, since I used for the purpose, not a bellows, but a Wattson's syringe. The other mode by which recovery sometimes takes place, though, doubtless, very rarely in infants, is sloughing of the incarcerated portion of the intestine, and its expulsion from the anus. In the two most common forms of invagination in infants, and especially when so extensive that the volvulus reaches to the anus, recovery by the

reduction of the displaced intestine is, I believe, a result quite impossible; so that, in such cases, if recovery takes place at all, it must almost of necessity be by the process of sloughing. Therefore, the mode of recovery of the above case being by reduction, and not by sloughing, of the bowel, is another reason why I believe the disease to have been located in the large intestine.

In conclusion, I have to thank Dr. Leaman for his kindness in having visited the patient with me, and also for some valuable suggestions.

THE FRACTURED SKULL OF A SUICIDE.

BY JARVIS S. WIGHT, M.D.,

Professor of Surgery at the Long Island College Hospital, Brooklyn, N. Y.

An unknown man, who died by his own hand, after being investigated by the Coroner and his jury, was brought to the Long Island College Hospital for dissection. He shot himself in the right side of the head, about midway between the eye and the ear. The skull of this suicide was on its way from the dissecting table to the field of the unknown dead, when the janitor, knowing my fondness for such specimens, stopped it in its journey and put it in my hands. This skull has points of practical and scientific interest, and I now propose to describe these points. The practical points come first, namely:

1. A lead ball, weighing forty-two grains, was found inside the skull, in the midst of decomposing brain substance. This ball was flattened and abraded on one side, and somewhat misshapen on the other side. The muzzle of the pistol which drove this ball into the suicide's head must have been very near the place of entrance. The effects were considerable and somewhat surprising, and may be enumerated as follows, namely:

2. Just above the right zygomatic arch an opening was made in the sphenoid and temporal bones. This opening was narrower in the middle than at either end. It was two inches long antero-posteriorly, and about one inch wide vertically.

3. The zygomatic arch was broken about its middle, and the superior maxillary bone was broken nearly through into the orbit, about half way between the alveolar process and the malar bone.

4. At the posterior extremity of the opening made by the ball, and about one inch above the external meatus, began a fracture of the skull, extending obliquely and irregularly backward and upward, nearly eight and one-half inches; the limit of the fracture was about three inches above and about one and one-half inches back of the left external meatus.

5. About four inches from the opening made by the ball, and one inch from the midline of the skull, the above noted fracture has a branch fracture running obliquely upward about three inches, to the midline of the skull.

6. At the upper angle of the anterior extremity of the opening made by the ball, and about one inch above the supra-orbital ridge, began a fracture, extending obliquely and irregularly upward and forward, across the frontal bone, about six inches. The limit of this fracture was four inches above and two inches in front of the left external meatus.

7. About three inches from the opening made by the ball, and three-fourths of an inch from the midline of the skull, the above noted fracture had a branch fracture running nearly directly upward and backward, two and one-half inches, to the coronal suture.

8. The two principal fractures went around the skull, leaving three and one-half inches of unbroken bone on the left side.

9. The two branch fractures left only two inches of unseparated bone on the top of the skull. The posterior branch fracture went into the sagittal suture, and the anterior branch fracture went into the coronal suture.

10. From the opening made by the ball the sphenoid bone was broken through irregularly, between the foramen rotundum and the foramen ovale, into the foramen lacrum medium.

11. More than one-half inch square of the posterior part of the external wall of the right orbit was broken out.

12. The basilar process and the condyles of the occipital bone were also broken out.

13. A fracture two inches long began at the posterior side of the foramen magnum and ran outward about one inch behind the right mastoid process.

14. On the left side a fracture extended from the foramen lacrum medium, directly across the glenoid fossa, into the external meatus.

15. From the left external meatus a fracture with two short branches extended upward and backward about one inch.

16. From the left external meatus a fracture extended forward and upward nearly five inches. The limit of this fracture was one inch above the left supra-orbital ridge, and seven-eighths of an inch below the main anterior fracture of the opposite side.

17. This suicide came near breaking his skull into three pieces by means of a pistol ball

weighing forty-two grains; showing the enormous energy of a pistol ball at a very short range, and, perhaps, the brittleness of an individual skull.

18. There were also a number of small pieces of this much broken skull.

19. It is possible that some of the injury to this skull was caused by the fall of the suicide after the ball penetrated his head.

And in the second place come the scientific points, namely:—

1. The base line measured five and one-eighth inches.

2. The transverse diameter measured five and sixth-eighths inches.

3. The antero-posterior diameter measured seven inches.

4. The circumference measured twenty and four-eighths inches.

5. The anterior arch measured twelve and one-half inches.

6. The frontal arch measured thirteen and one-half inches.

7. The middle arch measured fourteen inches.

8. The superior arch measured also fourteen inches.

9. The posterior arch measured eight and two eighths inches.

10. The masto-frontal angle measured about 70°.

11. This skull was so broken as to make it impossible to measure its cubic capacity.

It may be interesting to compare the dimensions of the skull of this suicide with the average dimensions of twenty-one Caucasian skulls, in the following table:—

Dimensions.	Average of 21 Caucasian Skulls.	Skull of a Suicide.	Difference.
Base line	4.843 in.	5.125 in.	$\frac{28}{100}$ in.
Transverse diameter	5.6 in.	5.75 in.	$\frac{15}{100}$ in.
Antero-posterior diameter	7.184 in.	7 in.	$\frac{18}{100}$ in.
Circumference	20.43 in.	20.50 in.	$\frac{7}{100}$ in.
Anterior arch	12.625 in.	12.50 in.	$\frac{12}{100}$ in.
Frontal arch	13.488 in.	13.50 in.	$\frac{1}{100}$ in.
Middle arch	13 565 in.	14 in.	$\frac{43}{100}$ in.
Superior arch	13.28 in.	14 in.	$\frac{72}{100}$ in.
Posterior arch	7.7 in.	8 25 in.	$\frac{55}{100}$ in.
Masto-frontal angle	75.5°	70°	5.5°

From the above table may be drawn the following conclusions, namely:—

1. The base line of the skull of a suicide is greater than the average base line of 21 Caucasian skulls, by $\frac{28}{100}$ of an inch.

2. The transverse diameter of the skull of a suicide is greater than the average transverse diameter of 21 Caucasian skulls, by $\frac{15}{100}$ of an inch.

3. The antero-posterior diameter of the skull of a suicide is less than the average antero-posterior diameter of 21 Caucasian skulls, by $\frac{18}{100}$ of an inch.

4. The circumference of the skull of a suicide is greater than the average circumference of 21 Caucasian skulls, by $\frac{7}{100}$ of an inch.

5. The anterior arch of the skull of a suicide is less than the average anterior arch of 21 Caucasian skulls, by $\frac{12}{100}$ of an inch.

6. The frontal arch of the skull of a suicide is about equal the average frontal arch of 21 Caucasian skulls.

7. The middle arch of the skull of a suicide is greater than the average middle arch of 21 Caucasian skulls, by $\frac{43}{100}$ of an inch.

8. The superior arch of the skull of a suicide is greater than the average superior arch of 21 Caucasian skulls, by $\frac{72}{100}$ of an inch.

9. The posterior arch of the skull of a suicide is greater than the average posterior arch of 21 Caucasian skulls, by $\frac{55}{100}$ of an inch.

10. The average masto-frontal angle of 21 Caucasian skulls is greater than the masto-frontal angle of the skull of a suicide, by 5.5°.

11. General conclusions: *This suicide had less than the average volume of brain in the anterior part of the cranial cavity. He had more than the average volume of brain in the posterior part of the cranial cavity.*

In fine, I regret that these are the only facts that I have of this case to put on record.

MOLAR PREGNANCY—AN ANOMALOUS CASE.

BY O. E. HERRICK, M.D.,
Of Michigan.

On the 15th of April last I was consulted by Mrs. D. for a persistent pain in the head, and occasionally attended, after three or four hours of severe pain, by paroxysms of frenzy, which would continue for from two hours to twelve or fourteen, when they would again gradually subside. These paroxysms were always attended by a feeling of fullness about the head. She stated, upon her first visit to my office, that she was pregnant about four months, and that her headache dated from about the time of conception; she believed that her headache and spasms would kill her if she was allowed to go to full time. I thought that perhaps it was but a *ruse* to get me to produce an abortion, and felt quite sure that such was the case when she added that she had importuned her usual medical attendant (a reputable physician) to produce an abortion to relieve her, and he had refused, telling her that

her headache and paroxysms of frenzy were entirely independent of her pregnancy. One thing which made me suspect, however, that the case was not a case of ordinary pregnancy, was, that she flowed a little at each monthly period, and her breasts were flaccid, although she was a woman of full habit, while she had leucorrhœa almost continuously.

I heard nothing further from her until May 2d, when I was called in haste to see her. I found her suffering severe pain in the head, face flushed, and with symptoms of mania well marked, although there were lucid intervals, but upon the return of pain she would again become violent. I gave her 20 grains of chloral hydrate every two hours, and fl. ext. of ergot, 15 drops, every hour (I gave the last to lessen the circulation in the brain). After the third dose of chloral she became quiet, and shortly dropped off into a sleep, and slept until about midnight quite naturally, when she awoke; and although she was still delirious, was much more quiet than before. She was given another 20 gr. dose of chloral, and in about twenty minutes again fell asleep, and slept until morning, at which time I again saw her, and found her rational, and suffering only slight pain in the head. I then made a vaginal examination, and found the uterus enlarged to about the size it should attain at a five months' pregnancy; but instead of having the hard feel of the pregnant uterus, it had a flabby, spongy feel; the os was dilated so that it readily admitted the finger, and I found that the neck was occupied by something which appeared to the finger like a piece of placenta. I introduced a gum-elastic catheter into the cavity of the uterus, and injected through it, with a common bulb syringe, about eight ounces of warm water; also continued the ergot. In about three hours I called again and found her flowing quite liberally, and undergoing pains at regular intervals. After waiting about an hour, and after a pain of unusual intensity, I made an examination, and found laying in the vagina a fleshy, fibrous mass, covered externally by a membrane, which might have been the decidua in a natural condition, while the inner surface of the mass was lined by a fine membrane, having the usual character of the amnion. After passing the mass, her pains suddenly stopped, and the flowing was only very moderate. I then left her, with instructions to take the ergot at longer intervals, about three hours apart. I called the next morning, and found she had passed three more, almost exactly like the first, about two inches in diameter, and she continued passing them for four days, until she had passed eleven of them, the last three of which I removed with the wire scoop; during all this time her flowing was quite moderate, and at no time severe. She made a rapid and good recovery, and has had no return of head symptoms since.

It is not an unusual thing for the uterus to be filled with a large number of vesicles of irregular shape and size, in the hydatid form of mole pregnancy. But it is, I believe, an unheard of thing for the variety described above to occur in such numbers, and each one entirely distinct from the other. It would seem as though a whole crop of ovules had been blighted, and that each one had commenced life with a distinct and separate placenta.

Another interesting feature of this case is the neurasthenia. The condition of this patient was exactly the opposite from the condition of patients said to be suffering from puerperal mania, as described by authors upon that subject. She was a robust woman, plethoric and strong, not weakened by hemorrhage or other abnormal discharges, except, perhaps, the leucorrhœa, and that had not weakened her, as her circulation was unusually strong during all her trouble. Authorities tell us that the cause of puerperal mania is anæmia, caused by hemorrhage, malignant disease of the uterus, abortion, etc., and is a disease which arises from great exhaustion. The question I wish to raise is, may it not occur from exactly the opposite condition; instead of the brain being anæmic, and not having enough blood supplied it, may it not have too much, as is the case in alcoholism, etc.? I believe both these conditions may produce maniacal excitement, and that one is as likely to produce it as the other, and hence the necessity of recognizing the difference of origin before commencing treatment. Diseases of the uterus, of all kinds, seem to exert a powerful influence upon the whole nervous system, and the brain being the great nerve centre, is especially apt to be more or less influenced by any severe or protracted disease of the uterus; it need not necessarily be pregnancy, nor need it occur only after a tedious delivery; but may, and frequently does, occur from any long standing inflammation or congestion of that organ; I have seen it in bad cases of dysmenorrhœa; I have also seen it as melancholia, in cases of displacements of long standing. We frequently observe it among frail married ladies living with strong and vigorous husbands, occurring from excessive coitus; the uterus is kept in a constant state of congestion, and the woman is converted into a maniac, and

hates the man she should love better than all others, and for no other reason than that her brain is influenced by her much-abused uterus. No matter what, in each individual case, the disease may be called, it is simply mania. The fact that the woman can no longer control her mind is sufficient evidence that she is insane. That point once settled in the mind of the attending physician, he should always look after the state of his patient's uterus. If he finds that his patient has recently passed through childbirth, and is suffering from puerperal fever, he should treat her for that disease. If his patient is in labor, and is attacked with violent pain, heat and throbbing of the head, which is greatly increased by her uterine pains, the cerebral excitement becoming intense, followed by furious delirium or convulsions, then he should deliver at once, and treat her for ordinary convulsions, which is but another form of this same class of difficulties. If the patient has dysmenorrhœa, and loses control of her mind, call it hysteria if you will, but it is uterine mania, just the same. Do not leave her to get well the best she may, but treat her dysmenorrhœa, and you will undoubtedly cure her mental difficulty. A patient with displaced uterus should have it replaced, and retained there after some common sense method. If the woman's husband is the cause of her trouble, either send him or her on a visit, and her peculiar form of insanity will probably vanish. In short, treat each individual case, and ignore the classes.

Medical Societies.

NORTHERN MEDICAL SOCIETY OF PHILADELPHIA.

(Reported for the Medical and Surgical Reporter.)

At the meeting in July, Dr. W. M. Welch read a paper, giving the history of a case of invagination of the large intestine, with recovery without sloughing (see page 221).

Dr. Stone remarked that invagination of the intestine generally occurred in young and feeble children, making the diagnosis perplexing and the treatment difficult. He recently attended a case of a male infant, who, on the second day after birth, was attacked with severe tenesmus, accompanied with great tympanites. The dejections were small in amount. A cathartic moved the bowels, bringing away, however, only a small amount of fæces, with but very little relief. He introduced a common gum catheter into the rectum and drew off a very large quantity of flatus, with temporary relief. This operation was repeated three times, with the same result. The post-mortem showed a congenital stricture of the colon, with a fold of the mucous membrane acting as a valve, nearly closing the gut. The case was not mistaken, but the symptoms closely resembled those of invagination, showing that we must be upon our guard in the diagnosis.

Dr. Eskridge had seen several cases of prolapse of the rectum which were reduced by hot water injections, after failing to reduce by the hand and by cold water. He reported the following case, and asked the opinion of the members: A middle-aged woman, in not very robust health, wife of a clergyman, was attacked with severe pain in the bowels, which disappeared as suddenly as it came, in less than half an hour, without medical aid. Three days later she had another attack, apparently the same, and the Doctor was called. One and a half grains of morphia failing to relieve, she was kept under the influence of ether for nine hours, when the severe pain suddenly ceased, only to be renewed after an interval of twelve hours. There was nausea and vomiting, chiefly of mucus. Temperature nearly normal (98° to 99°). She had been living upon liquid food for the past three years, saying that solids always gave her distress in the abdomen. There had also been a direct inguinal hernia, but there was no protrusion at the time, and no tumor could be felt in the abdomen. These paroxysms recurred daily, with little change, until the ninth day, when the vomiting became stercoraceous. Peritonitis set in on the tenth, and she died on the eleventh. No post-mortem was allowed.

There is a case reported in Watson's *Practice*, in which, after similar symptoms, a post-mortem revealed a gall stone, which had passed into the bowel, obstructing it at a previous stricture. He thought this case had a similar pathology. The suddenness of the seizure, together with the equally sudden relief, and the absence of all tumor, led him early to the diagnosis of hepatic colic, which diagnosis was concurred in by the consultant, Dr. Mills. He saw no reason for changing this opinion until the stercoraceous vomiting on the ninth day indicated obstruction. That there was a stricture somewhere in the alimentary canal, he thought was clearly shown by the selection of a liquid diet, and persisting in it for so long a period as three years.

Dr. Janney thought all the symptoms in Dr. Eskridge's case *might* have been from strangulation occurring in an old hernia returned into the cavity of the abdomen unreduced. He asked the question, why laparotomy should not be performed in all cases of invagination and internal strangulation from any cause. The experience of the gynecologists has proved that the operation is not in itself a very dangerous one. Some intussusceptions could not be redueed, yet others might be, and the extreme condition of the patient, he thought, would justify the attempt. He thought no surgeon would have refused to operate in Dr. Eskridge's case.

Dr. Rihl reported a case of a female, aged 79, who died of cancer of the stomach. The post-mortem showed, besides the tumor in the walls of the stomach, a large oval calculus, an inch and a half in the longer diameter, entirely filling the gall cyst; also a calculus of the shape and nearly filling the pelvis and calices of one kidney. He felt interested in these, because there was no

symptom during life that pointed to disease in either of these organs. The calculi were exhibited.

BRITISH MEDICAL ASSOCIATION—PROCEEDINGS OF SECTIONS.

In accordance with our custom, we give abstracts of the more important papers read before the Sections.

SECTION OF MEDICINE.

The first paper was read by Dr. H. Bennett, on

Mountain Air in Phthisis.

His conclusion was that recent experience at St. Moritz and Davos, as also at St. Paul's, Minnesota, United States, where hundreds of consumptives are now sent yearly, proves that phthisical sufferers may be exposed to intense cold, in the coldest regions of the earth, and yet do well, probably because they give up living in confinement in breath-poisoned rooms, and spend many hours daily out of doors. But it does not prove that these cold regions are the best for them. One fatal objection to mountain regions in winter in Europe, for any invalids, is, that from eighteen to twenty hours in the twenty-four must be spent in stove-heated rooms, and in bad weather the entire twenty-four. On the North shores of the Mediterranean, as on the plains of Central America, the phthisical patient may live in an atmosphere of pure air, with windows more or less open all the winter, day and night. The thermometrical conditions in-doors, in thoroughly ventilated rooms, with open windows, are about the same as those given for Quito, that is, they only vary between 56° and 66°.

Dr. Jagielski (London) said that a belief in the specific value of mountain air in phthisis threatened to become universal, and might probably lead to very one-sided views or other therapeutic evils. The Russian physicians were in the habit of sending phthisical patients to the Steppes of Tartary—a practice which was in opposition to the view of altitudes. The Tartar Steppes were sometimes not above, but below the level of the sea. Iceland had the same immunity from phthisis. It was said that this was because the inhabitants made use of a certain beverage, which consisted of a whey-like fluid, which they used to bottle up and bring to a fermentation; and it was said that no phthisis existed in Iceland up to the time of the introduction of tea and coffee. Something similar had been told of the Shetland Isles; so that, in fact, it was not altitude which was the particular influence.

Dr. George M. Beard read a paper on

Inebriety and Allied Nervous Diseases in America.

He stated that his interest in the subject was purely scientific; that he had been led to study the subject simply because it belonged to neurology—a department of science to which his life was devoted. Inebriety he defined as a functional disease of the nervous system; the chief, though not the only, feature of which is an irresistible desire for stimulants and narcotics, such as alcoholic liquors, opium, chloral, etc. Other accompanying and preceding symptoms are mental depression, mental irritability, insomnia, tremors, hallucinations, delusions, severe neurasthenia (nervous exhaustion), and in some cases, alcoholic trance. The disease inebriety is distinguished from the vice of drunkenness in four ways: first, by its irresistibleness; secondly, by its periodicity or intermittent character; thirdly, by its transmissiveness; and, fourthly, by the above nervous symptoms associated with it. The vice of drunkenness is objective; the disease inebriety is subjective. The disease inebriety has much the same relation to the habit of drunkenness that some forms of insanity have to eccentricity. The chief predisposing cause of inebriety is civilization. Savages, semi-savages and barbarians drink far more than enlightened nations, and the disease inebriety is always less frequent where the habit of drink is most common. The chief exciting causes of inebriety are alcoholic liquors, opium, chloral, etc. Another exciting cause is neurasthenia, or nervous exhaustion, particularly the form cerebrasthenia, or exhaustion of the brain. Brain exhaustion, which follows loss of property, bereavement, or sunstroke, may excite inebriety in one who is predisposed to that disease. In America, sunstroke is quite a frequent exciting cause. Injuries to the brain, as railway accidents and the like, may excite the disease; so also may salt air; some inebriates cannot go to sea, nor near the sea coast, without suffering an attack, with accompanying symptoms, such as headache, neuralgia, nervousness, etc. Inebriety is more common in America than in any other country, mainly from climatic reasons; dryness of the air and extremes of heat and cold. For the same reason other functional nervous diseases of the family to which inebriety belongs, such as neurasthenia, general neuralgia and hay fever, are more common in the northern and eastern parts of America than in the southern. Like every nervous disease of the family to which it belongs, it pretty steadily diminishes as we go south—go to the Gulf States; yet there is more total abstinence in the north than in the south. There is no country in the world where there is so much total abstinence from drinking, and at the same time so much inebriety, as among the people of the northern and eastern parts of the United States. The habit of drinking has been diminishing for the last half quarter of a century among the better classes, but the disease inebriety has been increasing at the same time among the same classes. Inebriety is to-day treated on the same principle as other nervous diseases of the same family to which it belongs; that is, first, by keeping the patient away from the exciting causes, and, secondly, by fortifying the system with sedatives and tonics. For very many cases asylums are indispensable, and legislation is needed, and in America is exercised, to give power of holding such cases. The best law, on the whole, is the law of the State of Connecticut, which is very similar to the "Habitual Drunkards' Act" which has just been passed by the English Parliament. The best remedies for fortifying the system and breaking up the habit of drinking, are bromides in very large doses (℥j to ℥ij), especially bromide of sodium;

electricity in general and central applications (general faradization and central galvanization), strychnine, quinine and cinchona, iron, cod-liver oil in emulsion, the preparations of zinc (oxide, bromide and valerianate), with warm baths. This system of treatment for opium inebriety, combined with the gradual withdrawing of the drug, has been wonderfully successful in America.

Dr. Wm. Squire, of London, followed with a paper on

Salicylic Acid in Rheumatism.

The iron treatment introduced by Dr. Russell Reynolds checked in some degree the febrile reaction, prevented subsequent impoverishment of the blood, and some of the worst consequences of endocardial exudation. Its use in erysipelas, and in rheumatism following some specific fevers and the puerperal state, is well attested. With children, cases may arise where a choice has to be made between iron and salicylic acid; one or the other must be adopted; they cannot both be employed at once. Dr. Squire's experience of iron was a favorable one. Twice in children, where the first signs of rheumatism were in the heart, this means, with chloral at night, gave good results. In one case, of a boy five years old, treated early with salicylate of soda, no heart affection occurred. In a girl three years old, with an endocardial murmur, and no joint affected when first seen, good progress followed the salicylate, but a soft systolic or presystolic *bruit* remained. The only evidence of the earliest attack of acute rheumatism in young children is often in the heart. Second attacks of acute rheumatism in adolescents have been treated very advantageously by either means. The change from profuse perspiration and great restlessness to comparative comfort, by the use of dyalised iron, in a young man with high fever, on the fourth day of other treatment, was very marked; good convalescence began in a fortnight. In a similar case treated on the third day with salicylate of soda, in twenty-four hours, before two drachms had been taken, all fever was subdued, and the convalescence began in a week. In second attacks, much prolonged, occurring to men at the age of fifty, one had pneumonia, one a systolic and cardiac murmur, and diffused pulmonary *râles;* rapid improvement followed the use of salicylate of soda. Cardiac irritation is always soothed under its influence; with a steadier circulation the *râles* in this case disappeared, diarrhœa, meteorismus, and perspiration ceased, and the urine, pale and of low specific gravity, as it often is in these prolonged cases, was soon restored to its normal quality. What none of the eliminative means used had been able to effect now occurred. An increase in the elimination of urea, noticed in favorable cases, is aided by the salicylate of soda; it acts as a sedative, without checking any of the secretions. The relief of pain is partly from its action on the central nervous system, more directly from the dilatation of the peripheral blood vessels which it produces; at the same time excitability of the heart is lowered; hence, its utility when the heart is already involved, while by its power to arrest the special febrile action, at whatever period of the disease it is given, no remedy can be so likely to prevent that complication. The earlier it is given, and the sooner its effects are produced, the less likely is the heart to suffer, for the shorter the duration of the fever the less is the possibility of heart disease. As salicylic acid is rapidly eliminated by the kidneys, the doses of it, or of salicylate of soda, must be frequently repeated. Salicine is but slowly and partially converted into salicylic acid. The acid is less easily and less safely administered than salicylate of soda, and is in no way more efficacious where no germicide influence is required. The acid so readily and cheaply obtained from carbolic acid, since Kolbe's great discovery, has exactly the therapeutic properties of that prepared by Cahors from the winter green (*Pyrola*) as determined in 1855 by Bertagnini. Salicine, as first separated by Leroux from willow bark, has been found by Senator and others to have no other action. The salicylate of soda is the readiest way of giving the remedy where its effects should be produced rapidly, a point of great importance in the young, and is exactly suited to what is required in the treatment of acute rheumatism.

His paper was discussed by several, and the President summed up the results of the discussion as follows: First, they had as yet no stable criterion whereby to determine the therapeutic effects of any drug upon rheumatic fever; they did not yet completely know the history of this fever. Secondly, therapeutic conclusions were apt to be vitiated by failing to distinguish between the two forms of the disease to which Dr. Southey and Dr. Sinclair had referred. Third, while the influence of salicylic acid and its compounds somewhat speedily relieved the *malaise* of which the rheumatic sufferer complained, it was extremely doubtful whether they in any degree diminished the peril of secondary cardiac or other inflammatory complications. Lastly, it was left uncertain whether they succeeded in removing that actual pathological state of which, in a sense, these other things might be said to be the expression. In short, there was almost a greater tendency to relapse with the salicylates than otherwise. Although this did not seem to be a very great gain, yet it was enough to help them in future inquiries.

(*To be Continued.*)

Danger of Pilocarpin in Obstetrics.

As this substance begins to be used in obstetrical practice, Dr. Hyernaux has read a paper at the Belgian Academy of Medicine, cautioning against its employment. He states that from his own experiments and the trials that have been made of it by others in their obstetrical practice, he has come to the conclusion that it exerts no special ocytocic action on the uterus, while it may yet induce abortion; and that it appears to him dangerous for the mother, and especially so for the infant. Prof. Müller, of Bern, who has made trials of the chlorhydrate, confirms these conclusions.

Editorial Department.

Periscope.

The Anti-febrile Effects of Cold Enemata.

In the St. Petersburg *Med. Woch.* of June 14th, quoted in the London *Medical Times and Gazette*, M. Lapin, one of the *internes* of Prof. Manassein's clinic, gives an account of the trials that have been made there of cold clysters as an antipyretic means. After noticing the few observations upon the subject which have already been recorded, he gives an account of the fifty observations which he has made in Prof. Manassein's wards. Of these he has published a detailed account in a Russian journal, confining himself in the present communication to a general statement of the results.

Prior to the administration of the clyster the temperature of the patient was taken, while lying on his back, in the axilla, the hypogastric region, and the rectum. The temperature of the liter of water employed varied from 5° C. to 10° C. (41° F. to 50° F.), and Hegar's apparatus at a pressure of two feet was used for the administration. After the water had been discharged the temperature was again taken in the same localities. Of the fifty trials, twenty-six were made on fever patients, twelve on patients with non-febrile diseases, and twelve on persons in health. From these trials the following conclusions are drawn: 1. Cold clysters form a practical means of reducing temperature, the influence of which continues for a considerable time. After clysters at 10° C. the temperature scarcely reaches its former height in the axilla for from thirty to forty minutes, in the hypogastrium after an hour, and in the rectum after an hour and a half. With clysters at 5° C. the cooling in the axilla lasts for forty or fifty minutes, but in the hypogastrium and rectum it lasts a much longer time than when water at 10° C. is used, so that the prior high temperature has never been observed to be regained until from two to two and a half hours after. 2. The clysters at 10° C. are well borne in all cases, without exception, sometimes leaving behind them a pleasant sense of coolness extending over the whole body. Those at 5° C. are by some just as well borne, but in others they induce unpleasant sensations in the abdomen. In recurrent fever even shivering may be produced. 3. The depression of temperature is more considerable in cases of fever than in non-febrile affections, and in the healthy. (In the fever patients the fall of temperature varied from 0.60° to 0.40° in the axilla, from 1.50° in the hypogastrium, and from 5° to 1.70° in the rectum. In non-febrile cases it varied from 0.40° to 0.30° in the axilla, from 1.40° to 1.10° in the hypogastrium, and from 1.60° to 1.30° in the rectum. In healthy persons, it varied from 0.60° to 0.30° in the axilla, from 1.30° in the hypogastrium, and from 2.60° to 1.40° in the rectum.) 4. Not only is the temperature diminished, but also the number of the pulse and respiration, to a small extent. 5. The greatest diminution of temperature takes place in the rectum; next in the hypogastrium, and least in the axilla. 6. An advantage of the cold clysters as an adjuvant of other energetic antipyretic means consists in their fulfilling other indications besides the depression of temperature: *a.* They remove the accumulation of masses of fæces, which so frequently occurs in fevers; *b.* They diminish meteorism by contributing to the removal of gases; *c.* In this way they render possible greater freedom in the movements of the diaphragm, and remove a source of self-poisoning of the economy by means of the gases; *d.* To a certain extent, they diminish the afflux of blood to the organs in the vicinity of the rectum, especially the uterus and bladder. 7. Stools follow the use of the clysters at different times in different individuals, varying from a quarter of a minute to two minutes and a half. 8. There can be no doubt that, when a clyster is also indicated in non-febrile cases, the cold clyster should be preferred to the warm in all those cases in which, besides the emptying of the intestine, it is desired to produce a tonic effect on the canal, or to diminish the amount of blood in the pelvic organs.

The Internal and External Action of Thymic Acid and Thymate of Soda.

Dr. Alvin, quoted in the *Practitioner*, from *Le Progrès Medicale*, has for more than a year substituted thymic for carbolic acid, in preparations which are used to produce a caustic, substitutive, or simply astringent action upon the mucous membranes of the larynx and pharynx. The solutions thus prepared are much better borne, and are at the same time much more active than those at present in use, and have given the most satisfactory therapeutic results. Thymic acid has the same curative properties as carbolic acid, and has a more pleasant smell. Some of the formulæ which extended use upon a large number of patients has shown to be capable of giving good results are here appended. Solutions for painting the parts may be made as follows:—

1. (*a*) Crystallized thymic acid, 1; pure glycerin, 2–4; (*b*) crystallized thymic acid, 1; iodine, 1; potassium iodide, 1; pure glycerin, 5–15.

2. Substitution solutions: (*c*) crystallized thymic acid, 1; pure glycerin, 50; (*d*) crystallized thymic acid, 1; iodine, 1; potassium iodide, 1–2; pure glycerin, 120; (*e*) crystallized thymic acid, 1; tannin, 1; pure glycerin, 100.

3. (*f*) Astringent solutions: crystallized thymic acid, 1; pure glycerin, 50.

4. (*a*) Pastils: thymate of soda, one milligram. To make a pastil of one gram.

For superficial stomatitis; irritation of the tract; softening of the mucous membrane in smokers; they are very efficacious in cases of spasmodic cough. They have also been tried in whooping cough.

(*b*) Thymate of soda, one milligram; chlorate of potash ten centigrams. For a pastil of one gram.

In severe stomatitis, tonsillitis, and pharyngo-laryngitis.

(*c*) Thymate of soda, 1 milligram; borax, 10 centigrams. For a pastil of 1 gram.

Ulcerated stomatitis and tonsillitis.

The pastils should be taken in doses of six to ten a day. They are calculated to remove the putridity of the parts which they are destined to cure.

5. Drink: thymate of soda, 1–4 centigrams; simple syrup, 61 grams; water, 100 grams. To be taken in twenty-four hours.

This preparation has been invariably used with success in affections of the lungs, the cough being lessened and the expectoration modified.

In cases of catarrhal bronchitis the disease has always been lessened in duration, and has been occasionally abated. Without stating that it is efficacious in whooping cough, Dr. Alvin believes that it will be found to be useful in that disease, judging from the effects produced on the few patients upon whom he has tried the remedy. Thymic acid has also been employed for inhalation, and in aqueous solution for cases in which naso-pharyngeal irrigation was indicated. It is also recommended as an exceedingly valuable modificatory agent. Thymic acid often contains impurities, and it is to obviate this imperfection that the crystallized acid is ordered. Thymate of soda is a very unstable salt, and requires great care in its preparation. Thymic acid, which is a powerful caustic, has hitherto been prescribed in too large doses (1 gram to 1.50 grams in twenty-four hours). Thymic acid was used in 1866, by Giraldes, in the treatment of wounds.

Treatment of Catarrhal Pneumonia.

Dr. Oscar T. Schultz describes, in the *American Practitioner*, his experience of this disease. On the subject of treatment he says:—

The remedial agents relied upon in the treatment of catarrhal pneumonia were belladonna, calomel, tartar emetic, quinia and whisky, given according to the following indications: When the fever was high, the mind blunted, the cough dry, infrequent, and perhaps painful, belladonna and calomel were given alternately every hour. If the fever remained high, above 101½°, for three or four days, a full dose of quinia was given in the evening. This was invariably followed by an almost normal morning temperature, and moist râles in the inflamed parts of the lungs; then tartar emetic or oxymel scillæ, with ipecacuanha, was continued until the lungs seemed clear. In all cases with high fever whisky was given regularly every hour or two, day and night, in one and a half drachm doses, until the fever abated. The cases which developed during whooping cough, or during capillary bronchitis, were usually treated with tartar emetic and belladonna, as in the following formula:—

℞.	Antimon. et potas. tartr.,	gr.ij	
	Extr. belladon., fluid,	gtt.iv	
	Pulv. glycyrrhizæ,	gr.lx	
	Aquam, ad.,	℥ iij.	M.

Sig.—One teaspoonful every two hours.

Or where there was more febrile action, calomel and tartar emetic were alternated every hour. The whisky was in these cases replaced by a light and nourishing diet of eggs and milk. Quinia was never used in these cases. In this way convalescence was usually established in the chronic form in from six to eight days.

In the catarrhal pneumonia of the aged, digitalis or tartar emetic, together with a treatment of the threatening symptoms, was employed; and if the fever was obstinate quinia was also used. With this course of treatment I lost six out of my twenty-eight cases, giving about 21.4 per cent. against 48.3 per cent., the mortality computed by Juergensen from the reports of five authors; and the results are even more favorable than my figures indicate, when we consider my record of deaths. For one was a man aged eighty-seven, in whom pneumonia supervened upon a chronic bronchitis; the second, a child of seven months, scrofulous, with habitual cough, and where the pneumonia complicated a pertussis; the third, a girl, aged two and a half years, with capillary bronchitis; the fourth, a child of ten months, without teeth, puny, in whom pertussis developed during a summer complaint, and pneumonia closed the scene with hydrocephaloid symptoms; the fifth, a boy aged one year, with pseudo-membranous laryngitis, in whom the lungs collapsed on the third to fourth day, and though the laryngeal symptoms abated, death took place on the fifth day; the last, a boy aged five years, in whom the diphtheritic exudation advanced upward and downward, irresistible as death itself.

The Treatment of Syphilis without Mercury.

Of a number of cases illustrating this treatment, given by Dr. J. P. H. Bodian, in the *British Medical Journal*, we quote the following:—

Case 1.—A. M., aged 32, had a solitary sore in grizzly induration. The occipital and inguinal glands were much enlarged. He had roseola and rheumatoid pains. He was treated in September, 1867, locally, by fuming nitric acid and water-dressing. The chancre healed in twenty-three days. Internally, he had iodide of potassium, nitrate of potash, compound ipecacuanha powder, and liquor opii sedativus. In February, 1868, he was looking well, and at duty. In March, 1871, he was in excellent health; and he continued so until he was discharged the service.

Case 2.—B. T., aged 20, had an indurated sore, roseolar and papular rash, psoriasis of the arms, and very severe ulceration of the tonsils. He was treated October, 1867, locally, by nitrate of silver and sulphate of copper. Internally, he had iodide of potassium, cinchona, and compound ipecacuanha powder. In May, 1868, he was in excellent health, and remained in good health until transferred to another regiment in February, 1873. I heard in 1877 that he was in good health.

Case 3.—C. J., aged 25, had an indurated sore, indurated glands in both groins, and roseolar and papular eruption, very marked and widely spread. He was treated in December,

1867. He was in very good health when he took his discharge, in 1871, and also by accounts lately received. The only local application was cold water; and the chancre healed readily, although the induration was very persistent. Iodide of potassium was administered in decoctum cinchonæ, and he had the usual hot baths.

I must state that all my cases of syphilis were treated by hot baths. Whatever variety there may have been in the use of other remedies, there was none in this. *Hot baths was the standing order for all cases of syphilis.* And, for the most part, the men were strictly confined to bed, often notwithstanding their entreaties to be allowed to get up. The most scrupulous attention was paid to the cleanliness of their linen.

Case 4.—D. W., aged 25, seven weeks previously to his admission for true Hunterian chancre, was under treatment for phagedenic ulceration of the prepuce. With the hard sore, he had indurated inguinal glands. The initiatory fever of secondaries soon appeared, and with it a dusky purplish papular rash, having a pustular tendency. The nates became covered with condylomata, and the scrotum before long looked like a piece of raw beef dotted with little patches of oyster shell. He was treated in December, 1867, locally, by sulphate of copper. Internally, he had iodide of potassium, cinchona, and Dover's powder. In May, 1868, his temperature was 98°, tongue clean, skin perfectly clear; there was not a trace of any rash, pimple, or sore. The scrotum was perfectly healthy looking. He was in robust health, and he continued so until he deserted, some years afterward.

Case of Temporary Amaurosis.

A curious example of this is given by Dr. C. E. Glasscott, in the *British Medical Journal*, July 19th. He writes—

The following case derives much of its interest from the circumstance that we have here a man in perfect health, and engaged in his daily avocation, suddenly plunged into the most utter darkness, and gradually restored to perfect vision, in the course of a fortnight. This occurred without the slightest morbid change observable in the eyes, and was not referable to any known cause; nor was it possible to suggest the cause of the blindness.

Thomas C., a miner, aged twenty-four, was brought to me suffering from sudden blindness. The previous history fails to throw any light upon the etiology of the case. There was no kidney or heart mischief, no evidence of syphilis, no history of fits, giddiness or other nervous symptoms. He never had had any disease, but a fit of colic four years ago, and had worked as a collier for the last fourteen years without losing a day's work from sickness; and the only accident he ever had was a small scalp wound on the occiput eighteen months ago. He had been a teetotaller for five years, and only smoked one ounce of tobacco per week.

I first saw him on January 27th, 1877. He stated his case as follows: On going to work at six o'clock that morning, his sight was perfectly good, and he worked at getting coal till 8.30, when he noticed suddenly that he was in darkness, and called out to his mate that his lamp had gone out, referring to his Davy lamp, which hung at a distance of four feet. He was told that it was burning brightly; but this he refused to believe until the lamp was handed to him, and he found it to be hot; he was then brought to the pit mouth, but he could not tell when he reached the daylight.

I saw him that afternoon, and found that, with his right eye, there was no perception of light from an argand burner, an inch and a quarter in diameter, at the distance of one foot; with the left eye he had the very faintest perception of light. The pupils were only moderately dilated; so I instilled some atropia, and made a careful examination of the whole fundus with the ophthalmoscope. The media were clear, the retinal vessels normal in calibre; the disk was rose-pink, and retina transparent; the region of the yellow spot was slightly more defined than in the normal eye; and the fovea centralis was a little redder in the right than the left. Next morning the quantitative perception of light had gone from the left eye, leaving him totally without perception of light. Both of my colleagues kindly examined the eyes independently, and corroborated my observations as to the apparent healthiness of the fundus. On the 29th I ordered one drachm of unguentum hydrargyri fortius to be well rubbed into each arm, and a couple of drachms to be worn in the axillæ, spread on lint. The patient remained in the same condition until February 5th, when he first complained of a metallic taste in his mouth. Next day his gums were distinctly spongy, and he said he could see the other beds in the ward indistinctly. On the 8th he was allowed to get up, and could see well enough to find his way about the hospital. Daily ophthalmoscopic examination found the appearance of his fundus unchanged. At his own request, on February 10th, he was discharged, and at once resumed his work; his vision at that date was the same with both eyes, viz.: V. $= 1\frac{20}{40}$ c $+ 24 = 1\frac{20}{20}$. The field of vision in each eye was perfectly normal.

Muriatic Acid in Typhoid Fever.

Dr. J. Y. Dale, of Pa., writes to the Boston *Medical Journal*, July 24th, 1879—

In treating typhoid fever I have become so impressed with the value of muriatic acid as a remedy that I wish to recommend it to the favorable notice of those of you who have not already given it a trial. My plan is to commence with the acid at the very onset of the disease, giving to an adult ten drops of the dilute muriatic acid of the Pharmacopœia every two hours. This is about half the ordinary dose, but a small dose is better borne by the stomach than a large one, besides being just as efficient. The acid should be given in an ounce or more of water, sweetened if the patient prefers it so, and to prevent injury to the teeth it should be taken through a straw or glass tube, or the mouth should be rinsed with a solution of soda. In mild cases, or at the commencement of the attack, this is generally the only medicine that is prescribed. I usually continue the acid through the whole course of the

disease, though at the beginning of convalescence the interval between doses is increased; but I am chiefly guided by the appearance of the tongue as to the proper method of giving it. If the tongue cleans and remains moist, and the digestion is good, with no diarrhœa or abdominal tenderness, it is no longer indicated; but if the tongue becomes dry or furred, it is immediately resorted to again.

I have used the acid plan of treatment for about twelve years. During the first few years I treated only part of my patients in this way; but for the past seven years I have used the acid exclusively, and in this time I have treated more than two hundred cases of fever, of all grades of severity, from the mildest to the worst form, without losing a single patient by death in my own practice. I have never yet lost a case in which the plan of treatment indicated in this paper was commenced early in the disease and continued without intermission. The acid seldom disagrees with a patient. I have given it under all circumstances, and to patients from three years old to sixty-five, being the extreme ages in which I have met with unmistakable cases of the disease. If it disagrees with the stomach I diminish the dose, or add a little deodorized tincture or wine of opium to it. Occasionally I have found it necessary to intermit the use of it for a day or two, but this was only in cases of great nausea, or where it was not properly administered.

Results of Antiseptic Surgery.

The results of antiseptic surgery at the Leeds, England, General Infirmary are thus summarized by the surgeon, Mr. Atkinson, in a late paper:—

1. Since the adoption of the antiseptic method in the treatment of compound fractures, the mortality had been reduced from 19 per cent. to 10 per cent. (the latter including several desperate and complicated cases which were beyond the reach of any treatment; so that if these were excluded the contrast in favor of antiseptics would be far greater). 2. The results obtained in operative cases had not been so uniform; *e.g.*, amputations, both primary and secondary, but especially the latter, had as often done well without as with the antiseptic precautions. The same might be said of excision of mammary tumors. On the other hand, resection of joints, subcutaneous osteotomy, the ligature of large arteries, removal of simple tumors, and the opening of abscesses, acute or chronic, or the aspiration of joints under the spray, yielded better results than could have been expected without. 3. The diminution or entire absence of surgical fever after operations done antiseptically was very striking. But the temperature, as a rule, rose, for the first twenty-four or forty-eight hours after operation, whether the case were treated antiseptically or not. This rise would vary according to the temperament of the patient, and could not be ascribed solely to surgical fever. 4. Lacerated and contused flesh wounds, when dressed antiseptically from the first, almost invariably healed without putrefactive pus, and with slight, if any, rise of temperature. 5. The use of drainage-tubes was a very essential element in the success of antiseptic surgery, allowing a free exit to the serous discharges, which, if arrested, caused an immediate rise in temperature; so that the thermometer was a certain gauge of the need for disturbing the dressings. 6. The experience of antiseptics in ovariotomy had not hitherto confirmed that of Dr. Keith; while a large number of cases of colotomy and strangulated hernia, very few of the latter of which, and *none* of the former, were done antiseptically, had shown a high average of recoveries.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——The literature of yellow fever is rapidly increasing in this country, and we cannot but believe that such careful studies will ultimately give us the mastery of the disease. Among the most recent issues is a series of "Reports to the St. Louis Medical Society, on Yellow Fever" (St. Louis, Geo. O. Rumbold & Co., pp. 320). These embrace the report of the committee appointed to inquire into the relations of the epidemic of 1878 to the city of St. Louis; a report of the meteorological conditions and etiology of yellow fever; the relations of malarial fevers and fevers generally to yellow fever; the theory and practice of the administration of veratrum viride in yellow fever; some remarks on cholera sporadica and sunstroke in St. Louis in 1878, etc. The work was prepared by Dr. W. Hutson Ford and the Committee of Publication. It has a number of maps, diagrams and charts.

Prof. Joseph Jones, of New Orleans, in a series of lectures on the disease, and in an elaborate paper in the *Transactions* of the Louisiana State Medical Society, discusses the treatment of yellow fever, and also its pathology as compared with malarial fevers. On the mixed question of introduction or spontaneous origin, Dr. Jones writes—

"No such marked differences exist between the climate of New Orleans and that of Havana and Vera Cruz, as would warrant the assertion that yellow fever is always endemic in the latter two cities, and that at the same time it cannot originate *de novo* in the former. While it is the wish of every true patriot to claim all excellencies of position and health for the land of his choice and love, at the same time, the future advancement of sanitary science and the highest interest of humanity demand that all causes of disease, whether existing in the soil or climate, should be honestly stated and fully weighed.

"Those who hold to the view that yellow fever never originates in New Orleans, but is *always imported*, must at least be forced, by the

past history of the great epidemics of this city, to admit that its climate and situation are such as to admit of the easy lodgment and rapid propagation of the seeds of this disease."

He believes that an enlightened system of quarantine, combined with the most careful sanitary and hygienic precautions, should be observed.

Another experienced observer, Dr. R. B. S Hargis, of Pensacola, has been contributing a number of articles to the Pensacola *Advance*, on the fever, and further proposes to publish at an early day a treatise on the disease, proving its origin to be in the holds of vessels sailing in tropical seas, which he believes will simplify the practical problem of how to stamp out the monster for all time. This treatise will embrace a description of the climate and diseases of all the district of country bordering the entire extent of the northern shores of Pensacola Bay, and extending one-quarter of a degree north. It also includes interesting historic sketches connected with the subject of the work. He says, in one of his already published articles—

"The facts of the early history of yellow fever indicate very conspicuously the maritime origin of that destructive malady, and show also, very clearly, its portability and mode of propagation from place to place, and forcibly suggest the necessity for the institution of different and more efficient measures than such as have been hitherto in operation, to prevent its intrusion into places where it does not hybernate, and, if possible, to cause its extinction everywhere."

The appearance of yellow fever in Chattanooga last year was a puzzle. Articles on it have appeared in the *Transactions* of the Tennessee State Medical Society, by Drs. E. M. Wight, G. A. Baxter and W. T. Hope. The latter concludes that—

"1st. Some other manner of introduction should be shown than that of personal introduction, *i.e.*, of a person divested of clothing, we might say, and simply sick of yellow fever.

"2d. That other ways of dissemination must account for the spread of yellow fever than that of personal intermingling."

The problem still remains unsolved, along with so many others about this terrible complaint.

——To confirm and establish harmony in the Profession is certainly a very desirable consummation, and to this end Dr. H. Genet Taylor, in a reprint before us, urges, beyond all else, to get at the exact truth of a story before falling into wrath about it. He says:—

"No medical man should make a charge against a brother of the profession, whether of medical error or of ethical unfairness, without having first had a personal interview, or by letter ascertained the actual facts of the injury or wrong, and the reasons he may present for his position.

"I am thoroughly convinced that by far the largest number of discords and wranglings, among gentlemen of our profession, arise from the failure to know the real facts, or to understand the reasons for the course that had been taken, and that a personal inquiry, direct from the parties interested, would, in many cases, show no cause of offence, or by an explanation of the facts, easily remove what might have been a slight matter, but would have become great, by the magnified power of repetition at second hand."

The philosophizing Obermann says, in one of his letters, that but two things are required to make men happy; first, that they should, in all instances, tell the exact truth, to their utmost ability; and secondly, that they should learn to predict the weather. Both he and Dr. Taylor are very largely correct.

——The Report of the House of Shelter, Albany, New York, for 1877 and 1878, is the record of a noble charity, devoted to rescuing women who are leading profligate lives, or who have become addicted to the use of opium or intoxicating drinks. Such an institution will have the sympathy and support of all who love their kind. But we cannot avoid expressing our regret that the Report is marred by such trashy writing as the following: "Satan has many ways of destroying the noblest powers of mind, and hindering those who might be eminently useful in the world. *Opium* has been one of his treacherous and covert devices of enslaving thousands. So adroitly has he carried on this scheme of human destruction, that his wretched victims really believe that this poison is a medical remedy necessary to relieve some bodily ailment," etc. Sound science and the cause of truth are not to be advanced by this sort of an explanation of the widespread love for intoxicants.

——In a reprint from the St. Louis *Courier of Medicine*, Dr. E. C. Gehrung explains an ingenious, and, in his hands, successful method of treating acute cystitis, by elevating and supporting the bladder by means of elastic tampons in the vagina. The same writer, in the August number of the journal mentioned, discusses at considerable length the forms of pessaries, giving preference to some of the later modifications of the Hodge pessary.

——Dr. Charles H. Thomas, of this city, urges, in a reprint, a general system of measurement for urethral, uterine, rectal and other instruments. He justly observes that a general scale, suited to this wide range of applications, and which shall combine the essential requisites of simplicity,

definiteness, and convenience of use, together with universal scientific intelligibility, is undoubtedly practicable. For this purpose it is only required that the use of all conventional numbers or sizes, as such, be abandoned, and that there be adopted in their stead actual circumferential or perimetric dimensions, expressed in terms of the metric unit; that is, in millimeters. The *adaptable metric gauge* which he used can be obtained through Messrs. J. H. Gemrig & Sons, of this city.

BOOK NOTICES.

On Asthma, its Pathology and Treatment. By J. B. Berkart, M.D. London, J. & A. Churchhill, 1878. pp. 264.

The paroxysms of asthma have been usually attributed to disordered nervous action, disturbance of the system, or the like. More and more, however, we are learning that all so-called "functional" disorders are etiologically associated with organic changes, and in this treatise Dr. Berkart undertakes to prove this in reference to the asthmatic seizure. By studying closely the condition of the patients between the attacks he has convinced himself that the disease commences with a more or less insidious inflammation of the pulmonary tissue, which passes on to bronchiecstasis and emphysema.

He begins his treatise with a history of asthma and a discussion of the prevalent theory regarding it; he then passes to its pathogeny, etiology and clinical history, its diagnosis and prognosis; and concludes by stating the general principles upon which its treatment may be advantageously conducted.

The volume is the result of a number of years of special study, and the author shows wide reading as well as careful observation. It must be named as one of the most valuable monographs on the disease which has appeared of recent years.

Materia Medica and Therapeutics. Vegetable Kingdom. By Charles D. F. Phillips, M.D., F.R.C.S.E. Edited by Henry G. Piffard, A.M., M.D. New York, Wm. Wood & Co., pp. 322.

In this treatise on materia medica the author classifies the plants used in pharmacy under their botanical classes, making no attempt at a physiological division. In this we think he is wise. In the first place, the physiological effect of drugs is a poor guide to their therapeutic powers; and a classification with regard to the latter must ever be incomplete, as so much depends on the size of the dose and other factors. His plan is to take up each plant, mention its active ingredients, and then, in separate paragraphs, its physiological action, therapeutic action, preparations and dose. Not much attention is given to the pharmaceutical or chemical relations of the drugs; and as the author inclines to what he calls "monopharmacy," he has little to say about synergistic, adjuvant and corrigent articles, in which, although he may, as he says, follow the prevailing fashion, he is probably on the wrong side. While generally abreast of his science, here and there the author seems behind it; for example, under salicine he says nothing of its employment in rheumatism or diarrhœa; and we have looked in vain, in the index, for any reference to *Œnothera biennis*, *Eucalyptus*, *Apiol*, *Asarum*, *Carica papaya*, *Dracontium*, *Erigeron Canadensis*, *Grindelia*, *Leptandrin*, and a number of other recent and important vegetable drugs.

The Heart and its Diseases, including the Gouty Heart. By J. Milner Fothergill, M.D., etc. Second edition, with illustrations. Philadelphia, Lindsay & Blakiston, pp. 476.

Seven years have elapsed since the first edition of this work appeared; so, as was required, the present one is announced as "entirely rewritten." Dr. Fothergill is a remarkably fluent and agreeable writer, and as he is also a devoted student, his works have all attained considerable popularity. Without embodying much original research, they are excellent compendiums of the present state of knowledge on a subject. Such is the one before us. He commences with a hardly necessary discussion of the anatomy and physiology of the heart, and a recapitulation of the physical signs and objective symptoms of cardiac disease. The sphygmograph is explained in a section by Dr. Foster. Then follow the various organic diseases, hypertrophy and dilatation, endocarditis, valvulitis, muscular degenerations of sundry kinds, rupture, angina, etc. Pericarditis and the neurosal affections have each a chapter. Sixty-odd pages are devoted to the gouty heart. Aneurisms and malformations are then discussed, and the work closes with a chapter on the elements of prognosis in heart disease.

An interesting feature of the work is the prominence which the author gives to pointing out the connection of various heart diseases with others of the general system, sometimes as cause, sometimes as effect. Too frequently monographs omit these most important relations.

The work is neatly illustrated and well printed.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

SOME RECENT INSTRUMENTS OF PRECISION.

The increase in the number of the instruments of precision insures greater accuracy in the diagnosis of disease and in our appreciation of the physiological functions. It is gratifying, therefore, to note the attention which has recently been devoted to their perfecting, and we shall briefly describe the more important of the novelties in this department.

The Audiometer. This instrument was invented by Prof. Hughes. It is a combination of the telephone, a new form of microphonic key, and a Leclanché battery. By its means the power of hearing sounds can be accurately gauged and recorded on a suitable arbitrary scale. The one in use is divided into 200°, the zero being the point of positive silence from the sound produced by the instrument through the telephone, and the maximum being audible to every one not actually deaf. The first point observed with this new instrument is that the power of hearing sound is very sharply defined. The sound is abruptly lost within a range of one hundredth part of the entire scale, both when the person can hear audibly and when he is more or less deaf. If the sound is suddenly moved from 15 to 5 on the scale, the weaker sound is inaudible, though if the scale had been gradually moved the sound at 5° would have been easily heard. Filling the chest and holding the breath increases the capacity for hearing for a few seconds. Holding the breath with the chest not full does not produce the same result. Most persons hear better with the right ear than with the left, but physicians who have accustomed themselves to use the stethoscope with the left ear hear better with it than the right; and four persons who habitually listened to public discourses from the left side also heard better with the left ear.

The Sphygmophone. This was suggested by the above and invented by Dr. B. W. Richardson. In this apparatus the needle of a Pond's sphygmograph is made to traverse a metal or carbon plate, which is connected with the zinc pole of a Leclanché cell. To the metal stem of the sphygmograph is then attached one terminal of the telephone, the other terminal of the telephone being connected with the opposite pole of the battery. When the whole is ready the sphygmograph is brought into use, as if a tracing were about to be taken, and when the pulsation of the needle from the pulse strokes is secured, the needle, which previously was held back, is thrown over, so as to make its point just touch the metal or carbon plate, and to traverse the plate to and fro with each pulsation. In so moving, three sounds, one long and two short, are given out from the telephone, which sounds correspond with the first, second and third events of sphygmographic reading. In fact, the pulse talks telephonically, and so loudly that when two cells are used the sounds can be heard by an audience of several hundred people. By extending the telephone wires the sounds also can be conveyed long distances, so that a physician in his consulting room might listen to the heart or the pulse of a patient lying in bed (speaking modestly as to distance) a mile or two away.

The Phonoscope. This is a device of Dr. Stein,

and is described and figured in the *Vierteljahrschrift der Artzlichen Polytechnik* for April. It is a small microphone, which is inserted in the clasp of a sound, and which, by connection with a telephone, renders audible all impressions which are required for diagnostic purposes. Thus it can be placed in a stethoscope, and thus define with great precision the cardiac and pulmonary sounds.

The Algesimeter. Such is the name applied by Dr. Björnström, of Upsala, to an apparatus he has devised for noting the sensation of pain or the sensibility of the nerve-fibers. It defines the point at which pressure is felt, not merely as such, but as painful, and measures this pressure in numbers. The pressure is exercised by pinching the skin, and hence the instrument may be used on all parts of the surface. It is composed of two slips of steel, one non-elastic, bearing at its end a dial plate and needle; the other, attached to the first slip, elastic, and approaching the first the closer as they are compressed at the free extremity, indicating this approach by the movement of the needle. When a portion of skin is caught and pressed between the two ends, the point where the compression becomes painful is noted on the indicator, and thus a means of compression is afforded in cases of sensory paralysis, etc., more exact than by any means that has hitherto been suggested.

Notes and Comments.

Therapeutical Notes.

PYROGALLIC ACID IN EPITHELIOMA.

Prof. Kaposi, of Vienna, has used strong pyrogallic acid as a caustic, and claims that its action is quite painless. In cases of epithelioma of the face, it was found to remove the diseased portions of tissue as thoroughly as arsenical paste, and did not affect the sound parts.

CHLORATE OF POTASSA IN CYSTITIS.

The value of this drug in chronic cystitis has been again emphasized by Dr. Zuccarelli, of Paris, in a recent thesis. It is by no means infallible, but it will always clear the turbid urine, soothe the pains, and stimulate the muscular contractions of the bladder. Even in cases where it does not induce a rapid and complete recovery, it will prove useful in affording the physician an opportunity of introducing a little variety into his treatment of cystitis. In some very serious cases, where the usual remedies had failed to afford relief, chlorate of potassa has been known to give good results. It is administered in two different ways, viz., by the mouth in very high doses; patients easily take 30 grams of it or more, only the precaution must be observed of giving the salt at meal times. The other method consists in injecting it directly into the bladder, beginning with a weak solution of 1.100, and gradually increasing the dose.

NIGHT SWEATS IN PHTHISIS.

Dr. Q. C. Smith recommends, as very efficient—

℞.	Zinci oxidi,	gr.j	
	Acidi pyrogallici,	gr.ij	
	Sulph. atropiæ,	gr.$\frac{1}{100}$.	M.

Sig.—For one pill. Dose i–ij, thrice daily.

EUCALYPTUS IN CHRONIC RHEUMATISM.

In this troublesome disease, Dr. H. Gibbons, Sr., of San Francisco, says that much benefit has been derived, in some instances, by wrapping up the knee, or ankle, or foot, with eucalyptus leaves, renewing them daily for a week or more. These leaves are an active stimulant to the surface, and will produce vesication if their use be long continued.

GELSEMIUM IN GONORRHŒA.

In the *Western Lancet*, Dr. J. Sullivan extols gelsemium as an unfailing remedy in the early stage of acute gonorrhœa. The fluid extract should be given four times a day, after meals and at bedtime, beginning with six or eight drops and increasing two drops every dose up to twenty drops, or until the patient experiences the peculiar intoxication, when it should be continued in smaller doses, as much as can be easily tolerated, for a few days, or till the discharge becomes lighter and disappears. An eighth of a grain of morphia is sometimes advantageously added to each dose. Saline purgatives, rest and abstinence, are essential parts of the treatment. After the acute stage has passed, copaiba and the oil of sandal wood will soon complete the cure.

Nausea in Pregnancy in the Lower Animals.

Dr. G. Law, of Colorado, sends us the following curious observation:—

"My brother, engaged in wool growing in our State, has a choice shepherd bitch, from which he breeds dogs for herding purposes. This animal, during all of her now three pregnancies, has for a considerable portion of each period manifested all the symptoms of pregnant sickness, nausea and vomiting after eating."

Poisoning by Mushrooms and Toadstools.

The narcotic and acid poison in these fungi is an alkaloid, called musarin or amanitin. It is very virulent. On Sept. 1st, at Elizabeth, N. J., a family of four children and their two parents ate some poisonous mushrooms; the parents were ill, but recovered; the children died. Mr. Palmer, of Boston, has an article on the subject in the Boston *Medical and Surgical Journal*, Aug. 28th. We have several times called attention to the assertion of Prof. Schiff, that the alkaloids of stramonium and belladonna, especially daturine, are efficient antidotes, and in Italy are kept chiefly for this purpose by apothecaries. Mr. Palmer desires the experiences of physicians on this form of poisoning. Muscarin diminishes blood pressure, partly by action on the heart, and also by dilating the blood vessels—also causes strong contraction of the intestines and bladder. It has been given therapeutically in doses of $\frac{1}{20}$ to $\frac{1}{10}$ of a grain; about half an hour after giving a dose we have profuse perspiration, contraction of the pupils, purgation, slight nausea and a desire to urinate.

Courage Comes by Degrees.

It is gratifying to announce that at least one medical journal, to wit, the *Medical Record*, has finally summoned up sufficient courage to intimate that if "some efficient system" of regulating prostitution is found, it would be well to adopt it. This is quite as much as can be asked at present. We presume that that estimable journal will agree to the truism that if no system is ever inaugurated, the "efficient" one will hardly be discovered. The *Record* at present seems to occupy the position of the old lady who forbade her boy going into the water until he had learned to swim! In attributing to us the wish to introduce the British Contagious Diseases Acts in their purest form, it is, however, in error; but we are strongly of the opinion that they would serve as an excellent model on which to begin legislation in limited districts.

Instantaneous Urticaria.

A curious case of what might receive this name is reported from Paris, in the clinic of M. Dujardin-Beaumetz. It was of a woman in whom the slightest contact gives rise to an urticarious eruption. Upon tracing his name upon her thigh the letters immediately appear in red relief, and this is accompanied by a local rise of from 1 to 2° in the temperature. There is complete anæsthesia of the whole body. Those who have studied the occult sciences know that this last symptom used to be a mark of demoniacal possession, and it will be remembered that the mother superior of the bewitched convent of London could produce on her arms the raised names of the devils who infested her body. A few years ago the spirtualists of Toronto used to communicate with their departed friends by the same means, through the arm of a servant girl of that city, and the medium, Foster, well known in Philadelphia and New York, can surprise his audiences with the same phenomenon, as we have been informed by eye witnesses.

The Radical Cure of Hernia.

The two latest surgical authors of this city, Drs. Agnew and Ashhurst, both speak unfavorably of the radical treatment of hernia. But apparently neither ever tried or witnessed the method advocated by Heaton in this country and Schwalbe in Germany. This is by injecting the substance of the rings so as to bring about adhesive inflammation. For this purpose Heaton uses extract of oak bark (see Napheys' *Surgical Therapeutics*, sixth ed.), while Schwalbe commends ethylic alcohol. In No. 61, 1879, of the *Algm. Med. Zeitung*, he gives a further and full account, both of his own experience and that of other surgeons who have tried the plan. The results are very favorable. We have previously described his method in the Reporter, but desire again to call attention to it.

A Sanitary Genius Wanted.

There is as wide a field in sanitary science for the efforts of genius as in any other direction. This is well illustrated by some remarks in a late number of the *Scientific American*. A writer says—

"Captain Eads has shown how the Mississippi can be entirely freed from the physical barriers which have hitherto impeded the commercial development of that noble water-way. But, however perfect the channel, commerce will not adopt a route liable to annual interruption by pestilence. Trade cannot brook diversion or delay. No more will it subject itself to liability to interruption. Of greater importance even than thirty feet of water is freedom from sanitary risks. Sand bars are but negatively harmful; pestilence is positive. The Mississippi must be made as healthy as the Hudson before its commercial possibilities will begin to be developed. Sanitary science must complete the work which engineering has begun. The great need of the Mississippi valley, commercially as well as socially, is a sanitary Eads. May he come speedily."

It is cheering to see the growing appreciation

of sanitary science which such remarks indicate. It cannot be too pointedly enforced on the public and on public men, that good health is at the foundation of all personal and national prosperity.

Prognosis in Smallpox.

In describing a case of smallpox, in the *Canadian Journal of Medical Science*, Dr. A. A. Riddell remarks—

Permit me to observe that where passive congestion sets in previous to the appearance of the eruption, in perfectly confluent cases, I have found that they invariably terminate fatally. I do not know whether this has been the experience of others who have had much to do with the disease. From what I have seen, I feel disposed to put them down as truly malignant, and I think I would not be altogether unwarranted in so doing. A fatal issue has generally supervened when this form of congestion has followed the appearance of the eruption in badly confluent cases. The blood, highly charged with the virus, seems to course very slowly through the vessels, and gradually to fill up the capillaries of the lungs. Position has little, if anything, to do with the production of this condition.

A New Anthelmintic.

In the *Cron. Med. Chirurg. de la Havana*, Dr. Lemos speaks of a plant known in Buenos Ayres as Albahaca, botanically the *Ocinum basilicum*, as a most efficient anthelmintic, superior to santonin, kousso or kameela. It has no poisonous effects whatever, excessive doses merely purging slightly. The ordinary dose is fifty grams of the juice, followed after two hours by a laxative.

Such is the story, as quoted with emphasis in the *Allg. Med. Zeitung*, of Berlin, July 26th. Now, if the *Ocimum basilicum* is meant, as no doubt it is, this is the ordinary "common basil," or "sweet basil," familiar as an aromatic, stimulant and nervine, but not as an anthelmintic. We await further developments, but suspect Dr. Lemos is the author or victim of a "sell."

Rules for the Examination of Seamen.

The disabilities which disqualify a seaman from going on active duty are stated by the U. S. Marine Hospital Service to be the loss of an arm or leg, defective vision, color blindness, epilepsy, mental unsoundness, hernia, piles, fistulæ, varicose veins, serious organic disease, habitual drunkenness, the existence of venereal disease, marked want of development, weakness of the body, or deformity. Any of these should cause the rejection of a seaman desiring to ship.

Tape Worms in Eggs.

Various instances have been recorded of the discovery in hen's eggs of minute specimens of the *distoma ovatum*. They appear like a small speck, the size of a millet seed or a pin's head. It is believed by helminthologists that these will develop into one of the varieties of tape worm, and it is wise, therefore, to take eggs hard boiled or otherwise well cooked. A writer in one of the late numbers of *Nature* cites several instances where these parasitic bodies have been found.

Correspondence.

Sewer Gas and Typhoid Fever.

Ed. Med. and Surg. Reporter:—

The Medical and Surgical Reporter has so wide a circulation throughout the country that I would not like anything to appear upon its pages that might create an erroneous impression in regard to my views, as set forth in my recent lecture upon the subject of "Sewer Gas, in Relation to Typhoid Fever," and read before the College of Physicians. The inquietude, anxiety, and alarm in the public mind, caused by the declaration that sewer gas was the most common and potent cause of typhoid fever in Philadelphia, was the principal motive for writing the lecture, and the main proposition of the paper is, that this declaration is in direct antagonism with the experience of those who have had most to do with typhoid fever, and is not supported by the returns from the Board of Health. Whether or not this proposition has been successfully sustained by the writer must be decided by those of the profession whose experience and mental capacity best qualify them for this purpose. The lecture contains nothing essentially new, and is merely a concise statement of what has long ago been recorded in the works of some of the most prominent members of the profession, and is fully in accord with my actual experience. The question of the possibility of sewer gas being, at any time, a cause, direct or indirect, of a certain proportion of typhoid fever, is not touched upon in the lecture, and a discussion of this point would, in its very nature, have been wide, discursive, and in the present status of professional opinion, inconsequent. As to the experiments of the redoubtable Dr. Rudolf Emmerich upon his still more redoubtable stomach, and those of his companions, it can only be said that they simply show that individuals are to be found whose digestive organs and imagination are proof against every assault. The writer trusts that "New Revelations in Sanitary Science" may be applied, in this instance, exclusively to the experiments of Dr. Emmerich.

Geo. Hamilton, M.D.

Philada., Sept. 8th, 1879.

Belladonna in the Treatment of Strangulated Femoral Hernia.

ED. MED. AND SURG. REPORTER:—

On the 15th of June, 1879, I was called to see Ike Thompson, aged twenty-seven, suffering intensely from a recent strangulated femoral hernia. It had developed a few hours previously, when lifting a heavy log of wood. All efforts at reduction by taxis, with aid of position and chloroform, failed; and the tumor had become so exquisitely painful that I concluded to operate as soon as possible. It being night, I secured the assistance of Dr. Visart for the next morning. In the meanwhile I directed him to take one grain of the alcoholic extract of belladonna every hour until ten doses were taken. I also fixed the patient immovably on a hard mattress, elevated his shoulders and pelvis, rotated his limbs inward, flexed them on the body, and applied a strip of Seabury & Johnson's Belladonna plaster, in rubber combination, firmly over the tumor, and for six inches above and below, drawing the integument strongly in the direction of the hernia. About midway between midnight and daylight "the thing slipped back," as the man described it, suddenly and very perceptibly, greatly to the relief of the patient, and, I confess, somewhat to my surprise. I attribute the result more to the local influence of the belladonna plaster than to anything else done. The plaster used was made by Seabury & Johnson, of New York, and in addition to its remarkable adhesive property, it contains more belladonna than any other I ever saw, as evinced by the powerful odor. Indeed, although I have been extensively engaged in the practice of surgery for twelve years, I do not see how I have managed to get along without the various plasters manufactured by Seabury & Johnson. Their isinglass and adhesive plasters, in rubber combination, are incomparably superior to all others I have ever used, in elegance, utility and durability. In fact, they are simply perfection, and every surgeon owes them a debt of gratitude, which I, for one, hereby acknowledge, as I see they are advertised in this journal, to which fact I am indebted for a knowledge of their existence.

DeWitt, Ark. J. B. GARRISON, M.D.

The Decimal and Metric System.

ED. MED. AND SURG. REPORTER:—

I was much pleased with Dr. C. H. Merrick's article on the metrical, or better, the decimal system, in a late number of the REPORTER. I, too, have adopted it, and find it so handy and simple, and withal, as much or more in its favor over the old system of grains, drachms, etc., as the United States notation of money is superior to the English system. I did not know, nor even did I think, there could be such an advantage in using the decimal system, until I read Dr. Princes' article in the *American Practitioner*. He there made it so plain to me that I resolved to adopt it, and thereby take another step toward progress and to be up to the times. He there says: "Any physician who writes prescriptions and wishes to adopt the metric system, has only to furnish his apothecary with a table of approximate equivalents. The simplicity of the scheme makes it easy to begin the use of the system without having the metric weights and measures. The dispensing chemist, with a table before him, can readily translate from the metric denomination into the apothecary's weights and measures." I then took the time and wrote out for my apothecary a table of approximate equivalents. The first thing was to make him understand that one gram was equal to fifteen grains, or one quarter of a drachm, and that .06 was equal to one grain. This done, the difficulty was about over, and I began at once to write my prescriptions in the decimal system, and, of course, compelled him to learn the new system. For, as Dr. Prince well says, "No apothecary will send a prescription to a competitor if he can translate it." As Horace Greeley said of resumption, "the way to resume is to resume," and, of course, the way to learn and to use the decimal system is to begin at once and use it. "For the habitual routinist," says Dr. Prince, "one mode is as good as another, once having been committed to memory; but for one who thinks of the powers and relations of his remedies, the advantages of the new system only need to be studied to be appreciated."

The relations, as to proportion, cannot readily be perceived, in the old system, without first reducing each separate quantity to grains; but in the new system there is no changing to do, for the relations show themselves on the face of the prescription. As an example, I take a few from the file:—

			GRAMS.	
℞.	Sacchar. alb.,			
	Gum acaciæ,	āā	16.	
	Ol. terebinth,		12.	
	Tr. opii,		4.	
	Aquæ camph, q.s. ad. cc.		128.	M.

SIG.—Teaspoonful every four hours.

The eye readily catches the proportion; for, dividing by 4, there is no remainder. In the old, it would stand as follows:—

℞.	Sacchar. alb.,			
	Gum acaciæ,	āā	℥ ss	
	Ol. terebinth,		f. ℥ iij	
	Tr. opii,		f. ℥ j	
	Aquæ camph, q.s. ad,		f. ℥ iv.	

A conglomeration of expressants.

Again—

		GRAMS.	OLD.	
℞.	Strych. sulph.,	.06	gr. j	
	Tr. digital.,	12.	f. ℥ iij	
	Tr. gentianæ,	16.	f. ℥ ss	
	Sp. eth. nit.,	32.	f. ℥ ij	
	Aquæ destil., q.s.,	128.	f. ℥ iv.	M.

SIG.—Teaspoonful three times daily.

Still more mixed up and hard to be grasped is this one in the old.

As I have said a great deal more, probably, than is said well, I will close the subject, to be agitated by more powerful minds, after asking a question, viz.: As the Convention for the revision of the United States Pharmacopœia is in session this summer, why would it not be the thing for the committee on that part of the work

to change the Pharmacopœia so as to read in the decimal system altogether. As that would be our authority, it would compel all druggists to learn the new system, and to provide themselves with weights, and thus put a stop to the whole discussion.

J. J. Connor, M.D.

Palmer, Ill., Aug. 29, 1879.

A Diagnostic Suggestion.

Ed. Med. and Surg. Reporter:—

In your issue of June 21st is an article, entitled "A Startling Case." The author (who withholds his name) gives us the details of the opening of a psoas abscess, and asks for the opinions of others as to the propriety of the procedure in this case. The danger in opening large cold abscesses, contemplated by Gross and others, is the exposure of the large suppurating surface to atmospheric air, after the pus has been evacuated. It is indeed a unique experience to observe the air rushing into an abscess before the exit of the pus. It presupposes the existence of a vacuum, which is altogether out of the question in psoas or any other variety of abscess. Probably if the doctors had used, instead of the "blister," a little judicious taxis, the "abscess" would have disappeared, and with it all the pain, heat and swelling. Afterward a properly adjusted *truss* would have been useful as a "prophylactic." The "frater medicus" was fortunate that his bistoury made so small an opening. The gut was just punctured, and the gush of air was *outward*, not inward, and "Deta" must have been suffering under a *cold in the head*, or he would have diagnosed the abscess by its odor. S. M. H.

Monmouth, Warren Co., Ill.

A Case of Congenital Hydrocephalus.

Ed. Med. and Surg. Reporter:—

On Sunday, August 20th, 1877, at nine o'clock P.M., I was called to see the following case, with Dr. C. A. Blount, of this place: The patient, Mrs. H. R., a stout, robust lady, was in her second confinement. When I arrived she had been in labor thirty-six hours. Dr. Blount, her family physician, had been called the day before to attend her. On his arrival he found, on examination, the os very dilatable and labor pains progressing at short intervals. As the patient's previous labor was not at all protracted, a lengthy labor was hardly anticipated. The first stage of labor continued for some hours, when the os was largely dilated and the distended membranes protruding into the vagina. The labor pains had all the time been hard and sufficiently frequent. Dr. Blount had, some time before my arrival, ruptured the membranes, which contained an excessive amount of liquor amnii. The labor pains still continued hard, but the uterus was unable to expel its contents. On further examination, we found the fœtal head, which we had previously diagnosed our presentation, but not without considerable difficulty, to be wholly unable to engage in the superior strait of the pelvis. We at this time diagnosed our case one of hydrocephalus, and as our patient's strength was becoming rapidly exhausted, and the fœtal heart was no longer audible, we concluded to administer chloroform and perform craniotomy. Dr. Blount perforated the fœtal head with Meigs' perforator, when our diagnosis was confirmed by the escape of four quarts, as near as we could approximate, of fluid, containing particles of the brain substance. The fœtal head now collapsed, when, with the craniotomy forceps, we easily delivered the body of a female child, weighing eight pounds, which possessed a large spina bifida in the lumbo-sacral region. The mother made a good and rapid recovery. In the case reported by Dr. Irwin, in the Reporter of August 9th, his presentation was a breech, and was not diagnosed as one of hydrocephalus until the body of the child was born. Decapitation was the only operation which could be performed with any degree of safety to the mother. All cases of hydrocephalus, however, are not breech presentations, and decapitation in such cases would be useless to think of.

Joseph N. Study, M.D.

Hagerstown, Ind., August 22d, 1879.

News and Miscellany.

The Yellow Fever.

The epidemic still continues its ravages, from twenty to thirty new cases being reported daily in Memphis, although the population of the city is so much reduced. On September 4th the Howard Association made an appeal to other cities for aid. The Memphis *Avalanche* frankly said that the city did not deserve assistance, because it had so neglected its sanitary condition. But the President of the Association reports a general willingness to assist.

Personal.

—M. Chevreul, now in his 93d year, began his usual course of lectures on organic chemistry at the Museum of Natural History, Paris, on June 10th.

—A gentleman writes from Edinburgh that the newly appointed Professor of Botany, Dr. Dickson, has a class of 450. The lecture room being quite inadequate to accommodate such a class, Professor Dickson is obliged to give two lectures a day.

—Dr. Oliver Wendell Holmes, in spite of his seventy years, is incessantly busy. He writes as much as ever, and is as interested in his duties at the Medical School. It is hinted that he intends to publish another volume.

—Dr. Luke P. Blackburn, of Louisville, was elected Governor of Kentucky, September 2d. He was charged during the canvass with being the physician of the same name and surname who, during the civil war, endeavored to infect Northern cities by shipping to them the clothes and bedding of yellow fever patients. This charge he neither denied nor confessed, declining to make any reference to it.

The Native Japanese Surgeons.

Dr. T. A. Palm, of the medical mission, Nugata, Japan, writes of the native practitioners there—

Some serious operations have been undertaken in the country, and the patients left in their charge. They have been instructed in the principles and practice of antiseptic surgery, but in some places have failed to carry it out. They are intelligent and fairly educated men, as a rule, that I have to coöperate with, and are anxious to improve in their profession. They have lately formed a society for the discussion of medical subjects and mutual improvement, and have requested me to preside over their meeting once a month, and give them a lecture on some medical subject. I have arranged to do so.

Items.

—At the annual meeting of the Adams County Medical Association, held in Gettysburg, Tuesday, September 2d, 1879, the following officers were elected to serve the coming year, 1879–1880: President, Dr. Isaac W. Pearson, of York Springs Borough. Vice Presidents, Dr. J. D. Weddelle, Bigler, P. O., Middletown, Adams Co., Pa.; Dr. J. M. Radebaugh, Gettysburg. Corresponding Secretary, J. W. C. O'Neal, M.D., Gettysburg, Pa. Recording Secretary, Dr. J. E. Gilbert, Gettysburg. Treasurer, Dr. E. W. Mumma, Bendersville.

—Not a single fatal case of trichinosis has ever been reported in England, although we export quantities of trichinous pork to that country. The reason probably is that the English like their rashers well cooked, while the Germans prefer theirs raw.

—A son of Thomas Sanford, of Farmersville, Collin county, Texas, died on August 19th, from hydrophobia. He was bitten by a pup, the mother of which had been bitten by a mad dog before the pup was born.

—The mortality in the famous new mining town, Leadville, Col., is very high. There are already more than two thousand graves in the cemetery. Pneumonia is the prevalent disease, and is said to be "sure death".

OBITUARY NOTICES.

—The Nestor of American medical journalists, Dr. J. V. C. Smith, died at Richmond, Mass., Aug. 20th, aged 79 years. In 1823 he started the *Medical Intelligencer*, the first medical weekly in this country. Up to 1856 he was editor of the Boston *Medical and Surgical Journal*, and later edited the *Medical World*. He was at one time Mayor of Boston, and, though never giving much attention to practice, was a remarkably well read physician. During the war he was Acting Inspector General at New Orleans. He also occupied at times the chair of anatomy in the Berkshire Medical College and the New York Medical College. As an author, in 1849 Dr. Smith published his work on the "Natural History of the Fishes of New England," and his exhaustive treatise on the "Anatomy and Physiology of the Eye." In this work, for a revised edition of which he had just arranged at the time of his death, Dr. Smith traces the development of vision in the animal kingdom, from the first crude optical organs of the invertebrates to the highly complex eye of the human family, marking each successive step of progress, and showing the relations of the simpler to the more complicated structure of vision.

—The Chicago *Tribune* records the death in that city, on August 29th, of Miss Sibelia F. Baker, M. D., a lady widely known there by reason of her recognized standing in the medical profession and her identification with numerous charitable and reformatory enterprises. The *Tribune* says that death in her case has cut short a career of usefulness and fame, and one which promised to demonstrate notably the possibilities of success to a self-made, self-reliant woman. In Vol. XXXVI of the MEDICAL AND SURGICAL REPORTER there appeared a well written article by her, on "Morbid Retention of the Dead Ovum."

QUERIES AND REPLIES.

Dr. J. C., of N. J., also challenges the statement of Dr. Simpson (page 169). Dr. "J. C." will observe that we did not guarantee this statement, because personally we know nothing about it; we do, however, consider it quite as likely as that Dr. Babcock, in over 400 cases, did not see a dozen of rigidity. Of course, the discussion can be made to turn on the meaning of words. Prof M. B. Wright, of Cincinnati, teaches that there is no such thing as rigid os!

Dr. W. M. D., of Texas.—Take it for certain that *all* opium antidotes are humbugs. They generally are simply disguised solutions of morphia.

Gumma.—Kerosene is no novelty in chronic rheumatism. Dr. Kemp (*British Medical Journal*, May 18th, 1872) states that several cases have lately come under his notice in which the internal administration of kerosene, a teaspoonful in water every other night, has had the most marked effect on this disease.

Dr. F. G., of Pa.—We do not care to publish many accounts of fasting girls, sleeping girls, snakes in the stomach, or popular cures of hydrophobia. There is no intellectual nourishment in any of these. Thanks to you, all the same.

Duval.—The original formula of Ricord's abortant injection in gonorrhœa is—

℞. Crsytallized silver nitrate, 50 centigrams
Distilled water, 100 grams.

Most writers agree that its employment is risky and unadvisable.

Secretary.—We shall always be glad to receive and publish abstracts of the proceedings of all regular medical societies, when of general interest, and shall thank you and others to furnish them. Extra copies of the number containing the proceedings will be supplied *gratis* to all members.

DEATHS.

HARDY.—In Cornish Flat, August 8th, Dr. Samuel Hardy, aged 74 years.

PORTER.—In New York City, on the 14th ultimo, Horace T. Porter, M.D., in his 32d year.

WRIGHT.—In Cincinnati, Ohio, on Friday evening, August 15th, 1879, at his residence, 357 West Eighth street, M. B. Wright, M.D.

DOCTOR RABUTEAU'S

(Laureate of the Institute of France.)

DRAGEES, ELIXIR & SYRUP

Of Proto-Chloride of Iron.

"The experiments made in the hospitals of Paris have demonstrated that *Dr. Rabuteau's Dragees, Elixir and Syrup* regenerate the red globules of the blood with a rapidity never observed with the use of the other ferruginous preparations. These results have been proved by the various *Compt-Globules.*

"The ferruginous preparations of *Dr. Rabuteau* do not cause any constipation, and are perfectly tolerated by the weakest persons."—*Gazette des Hospitaux.*

Dr. Rabuteau's Elixir is prescribed when some difficulty is experienced in swallowing the Dragees; it is especially adapted to weak persons, whose digestive functions need strengthening or stimulating.

Dr. Rabuteau's Syrup is especially prepared for children, who take it readily, because of its agreeable taste.

MEYNET'S

DRAGEES OF COD-LIVER EXTRACT.

Careful experiments have established the fact that the **EXTRACT OF COD LIVERS** contains very valuable properties, which render it superior to the ordinary cod-liver oil. It is composed principally of *Gaduine*, large proportions of *Iodides, Chlorides, Bromides, Phosphoric Acid, Lime, Soda* and *Ammonia*, and especially *Propylamin*, all of which enter, but in very small proportions, into cod-liver oil.

These dragees of pure cod-liver extract take the place of cod-liver oil, and have been used with eminent success by medical celebrities of Europe in cases of *Scrofula, Rheumatic Affections, Rachitism, Phthisis*, and in all cases where a propylamic medication is indicated.

MEYNET'S DRAGEES are sold in bottles containing 100 dragees. Dose, 2 to 6 a day. Each dragee is equivalent to two tablespoonfuls of cod-liver oil.

MEYNET'S GRAINS are small granules intended for children. 10 are equivalent to 1 dragee.

E. FOUGERA & CO., New York, Agents for the U. S.

RIGOLLOT'S MUSTARD PAPER.

Is one of the most important and useful discoveries of the age, but it is not (as certain dealers of bad faith pretend) a preparation that any one can make, for it is not manufactured with a mustard that every one can buy.

RIGOLLOT'S MUSTARD PAPER.

Is the invention of Mr. P. RIGOLLOT, who is the exclusive owner; it is the only preparation which has been adopted by the civil and military hospitals and the armies and navies of France and England, and which has obtained a medal at the Centennial Exposition at Philadelphia. All other mustard plasters or leaves of whatever name, are but imitations of the original

RIGOLLOT'S MUSTARD PAPER.

Physicians will find it the most reliable sinapism, prompt and certain in its action, and will therefore always prescribe it. Every sheet in order to be genuine must bear the annexed signature of the inventor, *P. Rigollot*

Sold in tin boxes containing 10 sheets, also 25 and 100 sheets, by all respectable chemists throughout the world.

E. FOUCERA & CO., Agents,

NEW YORK.

NEW REMEDIES.

FLUID EXTRACTS.

Coto Bark.—From BOLIVIA. Almost a specific in acute and chronic diarrhœa, cholera, cholera morbus, etc.

Cascara Sagrada.—(**Rhamnus Purshiana.**) From the PACIFIC SLOPE. A certain remedy for habitual constipation; and very useful in all cases where a laxative or cathartic is indicated. Beware of the fluid extracts of spurious varieties of this bark.

Folia Carobæ.—From BRAZIL. A powerful alterative, which exerts a marked curative action in syphilis, scrofula and kindred disorders.

Rhus Aromatica.—A remedy in diabetes, and other diseases of the genito-urinary organs.

Damiana.—(**Turnera Aphrodisiaca.**) From MEXICO. The best known aphrodisiac. Of great value in impotence, spermatorrhœa, and loss of sexual appetite.

Boldo.—(**Peumus Boldo.**) From CHILI. The new tonic. Very useful in dyspepsia, hepatic torpor, yellow fever, etc.

Berberis Aquifolium.—From CALIFORNIA. Has marked alterative and tonic powers, and has been used with extraordinary success in salt rheum, psoriasis, eczema, scrofula and syphilis.

Black Haw.—(**Viburnum Prunifolium.**) From the UNITED STATES. Employed to prevent abortion and miscarriage.

Grindelia Robusta.—From CALIFORNIA. A valuable curative agent in asthma and diseases of the air passages.

Grindelia Squarrosa.—From CALIFORNIA. Anti-malarial. Used in enlarged spleen and other malarial diseases.

Cereus Bonplandii.—(**Cereus Grandiflorus and Cereus McDonaldii.**) From MEXICO. Heart sedatives. Very useful in controlling functional and organic disturbances of the heart.

Kaki.—(**Diospyros Kaki.**) From JAPAN. Peculiar action on the mucous surfaces. Useful in mucous dyspepsia, typhoid fever, etc.

Cercis Canadensis.—Indigenous. A positive remedy in chronic diarrhœa, dysentery, etc.

Jaborandi (diaphoretic). **Guarana** (sick headache). **Fucus Vesiculosus** (anti-fat).
Bearsfoot (enlarged spleen). **Coca** (nervous stimulant). **Kava Kava** (Gonorrhœa).
Eucalyptus Globulus (antiseptic and anti-malarial). **Yerba Santa** (coughs).
Yerba Reuma (catarrh). **Wood Betony** (dyspepsia). **Ustilago Maidis** (oxytocic).
Penthorum Sedoides (catarrh). **Soap Tree Bark** (tooth wash).

CRUDE DRUGS.

Goa Powder (ringworm and diseases of the skin). **Gurjun Balsam** (a substitute for Copaiba).
Alstonia Constricta (a substitute for Calisaya).

SUGAR-COATED GRANULES.

Calcium Sulphide 1-10 gr. (for the cure of boils and carbuncles).

Our limited space prevents our describing in detail the history and application of each remedy, but to those interested in NEW REMEDIES, we will say, that we can furnish interesting information relative to the above new drugs.

PARKE, DAVIS & CO.,

DETROIT, - MICHIGAN.

Our New Remedies can be procured of the Drug Trade throughout the United States. By specifying **"P., D. & Co.'S"** in all cases, you will ensure reliable preparations of the **true drugs.**

COMPRESSED
Coated Tablets.

I ask the attention of physicians to the above new and elegant form of preparing medicines.

The discovery and successful application of the process of compression to the coating of medicines with a thin envelope of chocolate, sugar, etc., thereby avoiding the application of heat and the employment of tenacious pill-mass excipients, marks a great advance in elegant pharmacy, and fully meets the requirements of a refined taste.

The process is available for nearly every medicine, including, besides those articles adapted to pill and powder form, several others, such as Chloral Hydrate, Iodide and Bromide of Potassium and Pepsin; while for Quinine and other bitter and nauseous remedies it is unsurpassed.

Owing to their small bulk, thinness and lenticular shape, they may be easily swallowed, and are readily taken even by children.

All officinal and standard unofficinal formulæ for pills, etc., are put up in this new form.

The prices will correspond as near as possible to the best made pills and granules in the market.

Chocolate coating is used regularly, unless the sugar is ordered.

Send for samples.

LAWTON'S
ABSORBENT COTTON

FOR

HOSPITALS, DISPENSARIES, PHYSICIANS, DENTISTS, DRUGGISTS, PHOTOGRAPHERS, ETC., ETC.

The article furnished by us will be found superior to any other, on account of the facilities we possess for the manufacture, and the care taken at every step of the process.

Not only in general surgery, but especially in gynæcological practice, Absorbent Cotton has found great favor. It differs little from ordinary cotton in appearance, except in its uniformly fine quality and pure white color, freedom from all impurities — being entirely cleansed from oil, resin and all foreign matter.

The property of instantly absorbing liquids, its exquisite softness and great cheapness render it an invaluable substitute for Patent Lint, Charpie or Sponge.

We put up our Absorbent Cotton in neat and convenient packages, containing one pound, one-quarter pound, and two ounces.

A descriptive Circular will be forwarded on application. Samples containing two ounces will be sent, free of postage, on receipt of twenty cents.

PEPTONIC PILLS.

Pepsin, Pancreatin with Lacto-Phosphate of Lime and Lactic Acid.

(COPYRIGHT SECURED.)

This pill will give immediate relief in many forms of Dyspepsia and Indigestion, and will prove of permanent benefit in all cases of enfeebled digestion, produced from want of proper secretion of the Gastric Juice. By supplementing the action of the stomach, and rendering the food capable of assimilation, they enable the organ to recover its healthy tone, and thus permanent relief is afforded. One great advantage of the mode of preparation of these pills is the absence of sugar, which is present in all the ordinary Pepsin and Pancreatic compounds. In this form, the dose is much smaller, more pleasant to take, and is less apt to offend the already weak and irritable stomach. The results of their use have been so absolutely satisfactory, that we are confident further trial will secure for them the cordial approval of the Medical Profession and the favor of the general public.

Each pill contains one grain of pure PANCREATIN, which is equivalent to 10 grains of the ordinary or Saccharated usually prescribed and dispensed. Physicians will appreciate the great advantage of this mode of administration, the increased benefit to the dyspeptic being due to a full and effective dose of each, freed from unnecessary bulk, and really hurtful addition of sugar. A single pill will give immediate relief.

DIRECTIONS:—Take one pill immediately after eating or when suffering from Indigestion, Lump in the Throat or Flatulence. For children, reduce the pill to powder and give one-fourth or half, according to age.

MUSHROOM OR TOADSTOOL POISONING.

BY JULIUS A. PALMER, JR.,
Of Boston, Mass.

[This article, kindly furnished us by the author, was originally published, in nearly the same form, in the *Moniteur Scientifique*, Paris, Jan., 1879. The subject is so important and the information on it in text books so vague, that it cannot fail to be welcome to many readers.—Ed. Reporter.]

The terms fungus, mushroom or toadstool poison are synonymously used by mycologists. The three words may be so understood in this article. Mushrooms may poison the human system in three ways, as follows :—

1. They may simply disagree with the organs of digestion, as in the case of the hard, tough varieties of fungi, or in the case of the common mushroom, which, in a partly decomposed state, often generates hydrogen gas in such quantity as to produce nausea and vomiting.

2. They may be slimy, acrid or nauseous. Many mild *Boleti* are too slimy for food. The *Russulæ* have very acrid varieties. *Polyporus Squamosus* and others are bitter, and taste of leaves and grass.

3. They may contain a subtle alkaloid, without taste, smell, or other indication of its presence, as in the group known as the *Amanitas*.

The symptoms of poisoning by indigestion are soon manifest, and need occasion no alarm. Relief comes in the natural channels ; it may be hastened by emetics, by warm water, or by plunging the finger into the throat.

The effects of poisoning by some acrid or nauseous element are immediate, and present nothing to discourage physician or patient. Expulsion through the mouth or alvine canal, followed by emollients of sweet oil, slippery elm or gum arabic, will soon allay the irritation.

It is probable that most of the fatal cases of poisoning by toadstools are due to amanitine. Physicians have in all ages confessed their utter inability to find an antidote for this poison. An eminent chemist stated to me that he should regret to receive for test purposes the stomach of any one so poisoned, as he should not know where to turn for a reagent. This fungus being eaten has no burning or unusual taste. It passes harmlessly through the stomach, mixed with the other food. From eight to fifteen hours after ingestion, dizziness, nausea and purging begin, followed by fainting, delirium and death.

The foregoing classification is of great importance to medical men. Persons eating noxious mushrooms are, by that very fact, unable to identify the species that caused their sickness. Amateurs will often select six toadstools and class them as of one kind. Let the physician inquire carefully how much time has passed between the suspected meal and the attack. The shorter this elapsed time, the more hope for success by appropriate treatment. Poisoning by amanitine being the most common and most fatal, to this part of our subject shall the rest of this article be devoted. We shall cite three cases.

Two persons at Sautry, near Corbeil, France, made a meal from the *Amanita Bulbosa*, under which head the French include our *Amanita vernus*, *phalloides* and *mappa*, as but slight variations divide these three members of the group.

Beyond vertigo in one case, no ill effects were felt until three and eight, respectively, of the morning following. One patient even slept calmly after the vertigo passed away. Once attacked, however, the usual symptoms followed, and inside of three days both were dead. Space forbids an enumeration of their symptoms. Briefly, from attack to post-mortem appearances, these were little different from those of Cholera Asiaticum.

The physician understood the case, yet after the consecutive use of coffee, tea, antimony, ether, whites of eggs, anti-vomitives, laudanum, milk, leeches, ice and emollient fomentations, he says—

"None of the remedies were followed by the least sign of amelioration." He afterward excepts (as simple alleviatives) ice internally, and emollients applied externally to the abdomen.

A report of a more recent case, kindly furnished me by the consulting physician, is the second now before me. Any medical man would be struck by their perfect identity. Patients, attendants, and physicians seem to have assumed parallel parts in an equally sad drama. Four persons were poisoned in this case, of which number three died. The survivor's letter to me merits publication, and has been admired for its simplicity and clearness by many medical men. The fatal meal was eaten at four o'clock in the afternoon of Monday, October 2d, 1876. About midnight all were attacked who had partaken of it. The first death took place on Thursday following, at ten A.M. The second of the three on the next day, or Friday morning. The one who recovered experienced nothing but a severe diarrhœa. Her exemption and the latest of the three deaths will be the subject of future paragraphs.

The third and still more recent case is identical with the others. Details are, however, not at my command. Two of the patients were children, and died in thirty-six hours. One, the father, was subject to severe delirium, jumping from a second-story window. The attack came on about eight hours after ingestion. All these cases are alike in that up to the actual attack no person felt the worse for the fatal meal.

Mushrooms make the same use of the atmosphere as men; even their exhalations are, accordingly, air vitiated with their properties.

About four years ago a number of poisonous mushrooms (not amanitas, but of a totally different family) were sent me with edible fungus. The two varieties had lain twelve hours in the same box. The noxious ones were rejected, the esculent washed and eaten. In a moment my appetite was gone. Violent perspiration, vertigo and trembling were the next symptoms; then chills, nausea, purging and tenesmus, all within thirty minutes. Now, the substance could not have reached the bowels. The virus, absorbed from the noxious fungus, permeated the whole system through eating the harmless ones; unmixed with other food, it acted upon the muscles, through an empty stomach. Once spent, the attack passed off, and the substance, from which the system had absorbed all the venom, was digested without exciting undue motion when it reached the bowels. Probably this result was also due to the use of olive oil as a remedy.

Again, absorption may take place through the pores of the skin. An amanita held in the closed hand will produce all the symptoms of poisoning, even to convulsions. Once, while perspiring from a long walk, I undertook to bring in a large bunch of these mushrooms for an artist. Seated by them in a close car, holding them in my warm hand, although protected by a paper wrapper, a fearful nausea came over me. The toadstool was not at first suspected, yet I had all the symptoms of a sea-sick person, and was only relieved by a wide distance between myself and the exciting cause.

While writing this article, a friend sent me two very elegant specimens of the amanita tribe. They were in a confined box. On opening it, I smelt of them a few times and allowed the box to lie near my desk while I wrote to a medical gentleman anxious to procure such for chemical experiment. Having sent them away the matter was dismissed from my mind until three hours after, when an attack of vomiting and oppression at the stomach enforced it upon my attention. The whites of my eyes became livid, and even to noon the day following the leaden color of my face was noticed by more than one person.

One more example and we will draw the corollary, and speak of remedial measures.

This time I chewed a piece of an amanita the size of a half dime, ejecting the substance but swallowing a little of the saliva. Constriction of the muscles of the throat was the first symptom. One attack of vertigo followed, but it was momentary. Disgust with customary employment, like that felt in sea sickness was the most constant sign of the presence of the poison. Seventeen hours after swallowing it, I, for the first time, could have vomited, and felt a slight straining and tenesmus, after which the effects passed quickly away.

From these personal experiments the following conclusions may be drawn: The poisonous principle of fungus being absorbed by a harmless element, if the latter be eaten, the venom acts more quickly and surely. Additional proof of this assertion exists in the fact that if the amanita be cut in sections and laid in vinegar, the fungus may then be eaten without danger to life, but on a very small dose of the vinegar, death will follow more speedily than if the whole toadstool be eaten. One stage in the process of absorption has been completed. This last conclusion admits of one exception. In the second case of poisoning cited herein, a single member of the family escaped death. She put vinegar on the toadstool in her plate before mastication. The alkaloid was neutralized thereby, or at least fused with acid strong enough to occasion no harm excepting unusual action of the bowels.

But, after ingestion, any administration of remedies calculated to precipitate the alkaloid, or to amalgamate it with the gastric juices, only helps absorption and lessens the patient's chance of expelling it before his digestion has extracted all its venom. A dog poisoned with amanitine received vinegar as an antidote; his symptoms were all fearfully aggravated and great distress ensued. The presence of the assimilating agent simply aided the system in absorbing the virus. Sweet oil was given, when he vomited the fungus mixed with whitish mucus, and, on a milk diet, recovered.

Again, the inflammation, cramps, colic and straining at stool, do not cause the death of the patient, but are simply secondary effects of the poison absorbed. A few drops of amanitine injected up the back of a frog will produce death in one hour, without leaving on the body the slightest indication of inflammation. My most violent personal experience with this poison was when I was inoculated through the mucous membrane by the sense of smell alone. The oppression in the stomach and abdomen was very severe, yet not a piece of poisonous fungus lay in the intestines.

The poison by chewing a small piece shows how little may endanger human life, and further, that the operation through the digestive functions is so slow that any members of the amanita family should be tested with great care as esculents.

In speaking of the remedial measures it will be well to bear in mind that these remarks apply to the amanitas alone, the presence of which can be inferred by the physician, wherever the attack commences at eight hours or over after eating the mushrooms. Whatever the remedies used, they must be introduced into the system as *directly* as the physician's judgment may deem possible. The writer of this article is not a medical man, and he does not propose to dictate to those who have given drugs and their effects, the human frame and its wonderful network, their attention for many years.

Yet subcutaneous injections and enemata possess the most important qualifications for reaching poison by fungi. Two drugs may be suggested for hypodermic use; tobacco and atropine or belladonna.

The throbbing heart of a frog is silenced by a drop of muscarine; or Schmiedeberg's alkaloid from *Amanita Muscarius*. Action is restored by a drop of atropine. Animals who have been hypodermically injected with atropine are unharmed by a fatal dose of muscarine. Contrariwise, patients have eaten amanitas, and by means of emetics and purgatives every trace of the fungus has been removed. Stimulants and alleviatives have apparently built up the system; sixty hours after, præcordial distress, faintness, coldness of extremities and other symptoms have been manifest, proving that in rejecting the fungus the system had not discharged itself of the poison. By most mycologists, either emetics or cathartics are considered worse than useless in poisoning caused by amanitine. Injections of warm water, soap and water, perhaps mixed with oil of sweet almonds or oil of olives, on the contrary, relieve the tenesmus, and by producing motion in the lower intestines much assist the bowels in expelling the foreign substance in a natural manner.

Then the physician should use subcutaneous injections of atropine (which seems to control this most powerful of known poisons), or such other drug as the symptoms may indicate, or his discretion dictates.

Perhaps this article would be incomplete without a description of the leading traits of the amanita family of mushrooms. These are, first, a volva or wrapper, which encloses the young plant before it leaves the soil, and may be found at the base of the stem of the full-grown mushroom. The remains of this volva also appear on the cap or pileus, in the form of irregularly scattered and sub-persistent warts or scurf, easily rubbed off, leaving the skin intact. The gills underneath the cap are pure white, and if the mushroom is laid on blue paper a few hours, the white deposit of the spores will resemble delicate shading with an artist's pencil. The color of the mushrooms is very variable, red, orange, green, yellow and white, with intermediate

shades. The most common to this latitude is pure white or yellowish-white cap and otherwise pure white. There are several kinds which may be safely eaten, but it is far better for an amateur to avoid the whole group. The dangerous varieties are extremely common.

We make daily use on our table of a great many varieties of mushrooms for food, gathering them fresh in summer and drying the superfluous stock for winter use. Personal experiments prove that this constant use develops an extreme sensitiveness to the toxicological properties of fungi; the system does not become hardened to their noxious elements. Contrariwise, it repels them and is repelled by them in quantities which a stranger to such diet would not notice.

Because a mushroom is eaten with impunity by the lower animals, it by no means follows that it is fit for the food of man. In the case of October, 1876, mentioned herein, the amanitas were fed to the pigs, who ate the whole stew without ill effects. Swine are also proof against the noxious properties of *amanita muscarius*, and rabbits will swallow unharmed some other non-esculent fungi. On the other hand, *agaricus melleus* is said to have killed a dog in twelve hours, and a cat to have died in terrible convulsions from a meal of *marasmius oreades*. I have seen a dog very sick from biting off the tops of the *coprinus comatus*; all these are edible mushrooms.—*Moniteur Scientifique, Du Quesneville, Paris, Rue de Buce, 12th Jan.* 1879.

CHRONIC INDOLENT VARICOSE ULCER.

BY E. W. HILL, M.D.,
Of Glen Falls, N. Y.

I have been very much interested in the series of articles in the REPORTER upon Ulcer of the Rectum. Having been an interne in one of the largest hospitals in the United States, I know how unreliable hospital reports are (not from any intention of fraud, but oftentimes from the amount of detail work to be done in a given time), and sometimes the reports have to be made to please the visiting surgeon's hobby, and, therefore, I prefer those from private practice.

There is one form of ulcer that I wish to bring to the notice of the readers of the REPORTER—Chronic Indolent Varicose Ulcer. During the last two years I have had five cases, and every one of them had been pronounced incurable by a regular or quack physician, or both. In three of the cases a perfect cure has been effected, one was very much improved, and one is under treatment.

CASE 1.—Mr. W. R., aged about 50 years; has been a constant drinker of alcoholic liquors for over thirty years. Soon after the war commenced he enlisted. He contracted syphilis; was in the hospital long enough to get the primary sore healed, when he returned to his regiment. About 1868 he was kicked by a horse, and sustained a compound comminuted fracture of the leg. Soon after his recovery from this injury the ulcer appeared upon the outer malleolus of the leg. My treatment was, first to thoroughly cleanse the sore with a charcoal poultice, and then stimulate with balsam Peru and *tight* strapping. I continued this treatment for two months, with only slight improvement. I then put him upon potass. iodidi, ℥ ss. doses, three times a day, and improvement commenced at once, and he was cured in a month.

CASE 2.—Mrs. N., aged 48 years; has had two children; has had the ulcer upon her lower right leg for the last twelve years. Treatment was stimulating applications of balsam Peru, and occasionally pure carbolic acid and *tight* strapping; continued this for two weeks, with no change. We now applied, locally, cod-liver oil (and here let me say that in debilitated subjects you will find the oil to exert its beneficial effects in a truly wonderful degree, and very much quicker than when taken internally); still no marked improvement. I now removed, with a scalpel, the entire outer edge of the ulcer, which was a hardened, cicatricial tissue, and again commenced the balsam and *tight* strapping, when you could see the improvement from day to day. But she was unfortunate, and could not continue the treatment. Had she continued it a couple of weeks longer I believe there would have been a successful termination.

CASE 3.—Mr. A. R., aged 55 years; fine formed; very intelligent; active business man. About three years ago he noticed a pimple on the calf of his right leg; pricked it, and thought no more about it for some days, when he noticed that it had grown larger. Then he called the attention of his family physician to it, who was a homœopath. After some months of unsuccessful treatment, the patient went to Rome, N. Y., to the cancer doctors, but as they did not agree about the case, he came home and got in such a nervous condition that he had to give up business. He lived in this miserable condition, unhappy himself, and making every one about him the same. On Jan. 7th, 1878 he came and showed me the ulcer. I told him that I could cure it in less than two months, without the use of any medicine. He was very incredulous, and wanted

to know if any secret remedies were to be used. I told him none. Had him cleanse the ulcer with a charcoal poultice, and then I applied the balsam and strapped it tightly. It commenced to heal at once, and in six weeks he was cured.

Case 4.—Mrs. McM., aged 55 years; ulcer of thirty years' standing. She had been told by a number of doctors that it could not be cured. She called me, to see if I could do anything to relieve the pain, as it was very intense, night and day. She said that she could not tell when she had slept all night through, for the pain. I took off the sheet lead that she kept it covered with, and had a charcoal poultice applied that night, and I applied the balsam and *tight* strapping the next morning. She told me that after the pain from the tight straps wore off she had no pain, and was surprised to find that she had slept one night without being awakened by the ulcer paining her. That was the first night after strapping. Perfect cure in two months.

Case 5.—Mrs. K., aged 35 years; strong, healthy woman; had been troubled with the ulcer for three years. She did not call me expecting to get cured, as she had been told that it could not be done. She was going home the next morning, and so I could only dress it and have her husband continue the treatment—balsam and tight strapping. I have since received a letter from her, and I will copy a few lines: "It has healed about half, I should think, and is not very painful, except after doing it up. . . . . It looks quite like getting well, but I hardly dare to hope yet."

There is no reason why any one cannot cure a simple chronic varicose ulcer. If any physician has one that he considers incurable, if he will send it to me, if I do not cure it, I will return the patient free of charge, and pay traveling expenses.

Medical Societies.

AMERICAN DERMATOLOGICAL ASSOCIATION.

THIRD ANNUAL MEETING.

The third annual meeting of the American Dermatological Association was held in New York, on August 26th, 27th and 28th.

FIRST DAY.

After a brief private meeting for business, the regular proceedings of the Association were opened by an address from the President, Professor Louis A. Duhring, of Philadelphia, on

The Progress of Dermatology in the United States.

After alluding to the few scattered monographs and articles on cutaneous affections published in this country during the Eighteenth century, Dr. Duhring went on to depict the condition of dermatology in the period succeeding the Revolution.

Cutaneous diseases at this date were shrouded in the utmost obscurity, all, with few exceptions, being disposed of with the single general designation of "skin diseases," and even so eminent a physician as Dr. Benjamin Rush stating that "leprosy, elephantiasis, scurvy and venereal disease, appear to be but different modifications of the same disorder," and that "the same causes produce them in every age and country." About the end of the last century Hunter's work on the venereal was republished, being the first work of the kind which had appeared in this country, although syphilis had made its appearance in Boston as early as 1646.

With the close of the century we note the first of a series of admirable, and in some instances remarkable, theses, mostly presented in the University of Pennsylvania, on dermatological subjects, among which may be mentioned dissertations on the eruptive fevers and on rhus poisoning. Other essays on the physiology of the skin and on cutaneous absorption, followed, and in these the influence of the famous Dr. Rush upon his pupils is manifest.

Dr. Duhring continued, sketching the gradual progress of dermatology through the earlier years of the present century, and alluded to the ignorance and indifference which prevailed everywhere upon the subject. A student asking information upon a disease of the skin from a physician, received the reply, "Sir, I know nothing of skin diseases; you must go to the surgeon;" appealing to the surgeon he was met with, "Sir, I must refer you to the physician." The situation seemed hopeless. The whole subject was shrouded with a sort of mystery, and was deemed either too obscure or too insignificant to be worthy of serious attention. A few foreign works were translated, but nothing original appeared. The first institution devoted to the treatment of cutaneous affections was the "Broome Street Infirmary for Diseases of the Skin," in New York, opened June 22d, 1836, with Drs. H. D. Bulkley and John Watson in charge. The following year a course of lectures was delivered by Dr. Bulkley, being, it is believed, the first ever given on the subject in this country. The importance of the study of diseases of the skin was now for the first time beginning to be realized, and American students were seeking the hospitals of Europe, especially those of Paris, where, at the "*Hôpital St. Louis*," under Biett and Cazenave, clinical instruction in skin diseases was made highly attractive. Indeed, at this period there existed only one school of dermatology, that of Paris, and the influence of the French school was long felt in this country.

The first American work on diseases of the skin was "A Synopsis of the Symptoms, Diagnosis and Treatment of the more Common and Important Diseases of the Skin," with sixty colored plates, by N. Worcester, M.D. Philadelphia, Boston, Cincinnati, 1845. Dr. Worcester was Professor of Physical Diagnosis and General Pathology in the Medical College of Ohio, at Cleveland. His work was a mere compilation.

The plates were much reduced in size, and very imperfectly reproduced. About this time, and later, a number of foreign works were brought out in this country, chiefly translations from the French. The year 1853 was marked by the creation of special departments in skin diseases at various dispensaries in New York, and at the Howard Hospital, in Philadelphia. Students of dermatology, well qualified by long sojourn abroad, and deeply interested in their work, were now (1860–70) beginning to return from Europe, and to enter upon the field as instructors and lecturers. Paris and her long line of famed teachers, who for so many years shed lustre on the "*Hôpital St. Louis*," no longer claimed the exclusive attention of American students. One now began to hear on all sides of the teachings of the eminent Viennese dermatologist Hebra. Students flocked to Vienna from all parts of the world, eager to listen to the words of a teacher who was able to unfold and explain in plain language these hitherto obscure diseases. Among the number were a few Americans, who, after several years' study with Hebra and his distinguished confreres, returned home well prepared to teach the principles of the new dermatology, the practical value of which they were not slow to recognize. Among the earliest of these was Dr. J. C. White, the former President of the Dermatological Association, and for some years past Professor of Dermatology in Harvard University. In addition to numerous articles in the journals, Dr. White, as early as 1861, gave the first lectures on Dermatology in Harvard University. Following the close of the late war numerous clinical professorships and lectureships were established in different medical colleges.

The translation of Hebra's work marked an important epoch. Great confusion existed in dermatological writings, and particularly regarding nomenclature, and it needed a strong hand to reduce what threatened to be chaos to order. English nomenclature in particular, represented by Wilson, added not a little to the confusion of the time. Especially trying was it that this authority, whose works had been so largely read in this country, should have abandoned himself to the demolition of his own nomenclature. New words were coined to take the place of old, tried and well-known terms, and the spelling of many names was so changed as to render them barely recognizable. As an instance, no less than five names were in turn proposed by Mr. Wilson for the disease we now know (and let us hope may ever know) as psoriasis; lepra, psoriasis, alphos, lepra alphos, and lepra Græcorum were all tried, and sooner or later rejected. These numerous and constant changes, actuated by whatever motives, emanating from so high an authority as Mr. Wilson, were certainly disastrous in their results. A brief but trenchant article published at this time (1870) by Dr. J. C. White, entitled "An Amusing Chapter in Nomenclature," showed in what an unenviable position Mr. Wilson had placed himself.

While the labors of Hebra did much to simplify nomenclature, it has been left to the American Dermatological Association to accomplish very much in this direction for America. The earliest Dermatological Association in this country is the New York Dermatological Society, founded in 1869, which has done much good work. In 1870 was started the American Journal of Syphilography and Dermatology, edited by Dr. M. H. Henry, which was continued through five volumes, containing many original and valuable articles, and was succeeded by the Archives of Dermatology, which, under the editorship of Dr. L. Duncan Bulkley, continues its work as an exponent of American Dermatology. In 1876, at the International Medical Congress, held in Philadelphia, the plan of this association was formed, which now represents in its membership the dermatologists of every section of our country.

In conclusion, Dr. Duhring said he should have been pleased to have continued his subject to the present day, but the vast accumulation of material rendered this impossible at the present time.

Following the address by the President, came a paper by Dr. I. E. Atkinson, of Baltimore, entitled "*A Case of Incomplete Vitiligo*," the patient being a mulatto woman, in whom the chromatic changes accompanying this disease displayed somewhat unusual symptoms, and ran a peculiar course. Dr. Jas. Nevins Hyde, of Chicago, then read a paper entitled "*A Contribution to the Study of the Bullous Eruption Induced by the Ingestion of Iodide of Potassium.*" At the afternoon session Dr. L. Duncan Bulkley, of New York, read an account of "*Two Cases of Chancre of the Lip, Probably Acquired Through Cigars.*" A very interesting discussion on the propagation of syphilis by unusual means followed the reading of this paper; cases were cited where the disease had been carried by means of tooth brushes used in common, towels etc. Dr. Sherwell, of Brooklyn, described the method of cigar manufacture in Havana, where women of the lowest class, and of filthy habits, are accustomed to roll the cigars on the inside of the thigh, in the course of which manipulation the cigar could easily come in contact with the secretions from the genitals, etc. Dr. Bulkley said he had been informed by the head of a large cigar manufactory, that, although machines were at hand for the purpose of finishing the rolling of the cigar, workmen would persist in using saliva for this purpose. Several of the members objected to the title of Dr. Bulkley's paper, believing that the source of infection in the cases described had not been proved to be derived from an infected cigar. It was suggested that the title of the paper should be amended, so as to read "possibly acquired through cigars."

Dr. George H. Fox, of New York, read a paper entitled

The Treatment of Eczema and Ulcers of the Leg by an Elastic Tubular Bandage.

He had frequently found, he said, that the "solid rubber bandage" of Martin, so far from doing good in eczema of the leg, frequently did actual harm. This occasional untoward result sometimes depended upon faulty manufacture, but very often upon the unequal pressure and cutting edges of the folds of rubber sur-

rounding the limb. He had devised a thin, hollow tube of rubber, about twenty-five centimeters (ten inches) in length, with an average width, when flattened, of eight centimeters (three inches), and of varying thickness. This can be drawn over the naked limb, prepared only by oiling it, or dusting some finely powdered starch over it. The tube should reach from the ankle nearly to the knee. It is unnecessary that the foot should be covered, unless the disease has invaded it also, in which case a longer tube, with an opening to give room for the heel, or two tubes, may be used. He showed one of these tubular bandages in position. It had been worn several days without the least discomfort; there was no tendency to undue sweating, nor to maceration of the epidermis.

The last communication of the day was in the form of a lecture, by Dr. Charles Heitzmann, of New York, on "*Microscopical Studies on Inflammation of the Skin.*" This lecture, which was abundantly illustrated by sketches thrown off by the speaker while addressing the Association, was supplementary to that delivered before it last summer, at Saratoga, on "The Behavior of Epithelium," and was a masterly effort.

SECOND DAY.

After the usual business meeting, the public session of the Association opened with a paper by Dr. H. G. Piffard, of New York, on "*Viola Tricolor.*" The fluid extract of this plant, which belongs to the pansy family, was asserted by Dr. Piffard to be efficacious as a remedy in infantile eczema capitis.

In the discussion which followed the reading of this paper, Dr. Heitzmann said the remedy was an old one, and one of a numerous class which had been in vogue in Germany since time immemorial, until Hebra dispelled the mists of darkness which hung around dermal therapeutics, and showed that these so-called vegetable specifics had no more curative effect on skin diseases than so much hay.

A paper followed, by Dr. Arthur Van Harlingen, of Philadelphia, entitled "*A Case of Chronic Inflammatory Tuberculo-vesicular Disease of the Skin,*" with illustrative microscopic sections of the lesions. The last paper of the morning was by Dr. Samuel Sherwell, of Brooklyn, on

The Tattooing of Cutaneous Nævi.

Dr. Sherwell described the peculiar method devised by himself for performing the tattooing process, and described the apparatus which he had invented for the operation. The instrument consists simply of half a dozen fine glover's needles, bound together in a bundle with waxed thread, so that their points shall be one to two millimeters apart. This is used either alone or in connection with some irritating substance, as carbolic acid. Many sittings are required, and the operation is a painful one, but the results are satisfactory in all cases of superficial or cutaneous nævi. Of course, when the nævus is of considerable size and deep, and is supplied by large sinuses, this method cannot be practiced. At the conclusion of his paper, Dr. Sherwell brought before the association a female patient, upon whom he had operated by tattooing, for the relief of a disfiguring nævus of the chin. The cure was not quite completed, but thus far the success was undoubted, and the result of the tattooing treatment could not fail to be ultimately satisfactory.

AFTERNOON SESSION.

Dr. W. A. Hardaway, of St. Louis, read a paper giving an account of "*A Case of Multiple Tumors of the Skin Accompanied by Intense Pruritus.*" Dr. Duhring read a paper entitled "*Supplement to a Case of Inflammatory Fungoid Neoplasm,*" being a continuation of the history of the case presented at the previous meeting of the Association. Considerable discussion followed the reading of this paper, the question being as to whether the disease deserved an especial name, or whether it might not be classed among the sarcomata. The last paper of the afternoon was one by Dr. James Nevins Hyde, of Chicago, giving a description of "*A Variety of Molluscum Verrucosum, Presenting Unusual Features.*"

THIRD DAY.

The papers read at this, the final, session of the meeting were three in number. The first was by Prof. Jas. C. White, of Boston, on

Etiology.

The reader examined the various theories formerly, and perhaps still, prevalent regarding the dependence of diseases of the skin upon diatheses, and upon affections of the various organs, etc., and claimed for the skin the same independence with regard to the causation of disease which is allowed to other organs of the body. An animated discussion followed the reading of this paper. While all the speakers praised the skill and thoroughness with which the reader had disposed of the crude and theoretical views formerly prevalent, and still, perhaps, somewhat in vogue, by which skin diseases were regarded as the efforts of certain humors to break out of the body, or as the outward manifestations of some mysterious diathesis, yet much opposition was expressed to his views upon the independence of the skin of the diseases and ailments of the various internal organs. Dr. R. W. Taylor's paper "*On the Nature of Syphilis,*" took the ground that certain minute albuminous protoplasmic bodies found in the serum of chancres and other lesions of early syphilis act as carriers of contagion. The final paper of the session was a second one by Dr. Hardaway, of St. Louis, entitled "*Obliteration of Varicose Vessels in Rosacea by Electrolysis.*" Dr. Hardaway described the apparatus made use of by himself, consisting of a number thirteen cambric needle inserted to the depth of 1.5 to 2 millimeters into an opening first made in the dilated capillary, and connected with a battery of seven cells.

After a short discussion upon Dr. Hardaway's paper, the Association adjourned to meet next year in Newport, on the last Tuesday in August, 1880. The officers for the following year are, President, Dr. Louis A. Duhring, of Philadelphia; Vice-presidents, Drs. E. Wigglesworth, of Boston, and W. A. Hardaway, of St. Louis; Secretary, Dr. Arthur Van Harlingen, of Phila-

delphia; Treasurer, Dr. I. E. Atkinson, of Baltimore.

BRITISH MEDICAL ASSOCIATION—PROCEEDINGS OF SECTIONS.

SECTION OF MEDICINE.

(*Continued from page* 229.)

Several papers were read on

Alcohol in Fever,

Expressing quite different opinions as to its value as a medicine and accessory food.

In the discussion, Dr. Spedding (Belfast) said he had considerable experience in the administration of stimulants to children in a variety of diseases, chiefly high pyrexiæ and fevers. Only one speaker had alluded to giving stimulants to children, and he seemed to be rather averse to it. He had cases in which, for several days, children had not allowed one particle of nutritive food to enter their stomachs, and had lived on nothing but water and punch, made very sweet and taken cold. It had been his practice for the last eight years, in the Belfast Dispensary, to withhold alcohol till pulmonary complications appeared, about the second or third week. He thought that was the time when the use of stimulants was indicated; and then he measured the amount of his stimulants by the amount of the pulmonary complications. It seemed to act remarkably well on the heart, and also acted as an expectorant.

Dr. Smith, of Dumfries, said that in Scotland they recognized fever as a disease that ran a certain course. They found that the best method of preventing death was to support the system from the commencement of the fever; and they did not give stimulants when they found that nervous symptoms were produced.

Dr. Sinclair (Dundee) was of opinion that the other ingredients of most alcoholic fluids were not by any means to be under-estimated or ignored, as they too often were. Whisky contained none of those volatile ethers which were developed by keeping in the rich wines of France and Spain; and for this reason he objected to the administration of whisky.

Dr. Little (Dublin) wished it not to be supposed that he thought alcohol was not one of the most valuable agents they had. He had, however thought it was potent for evil as well as for good; and that they must be exceedingly cautious in its use. He had himself been in the habit of prescribing a cup of tea in the morning, beaten up with the yolk of an egg, as a substitute for stimulants.

The President said this had been the most satisfactory discussion on a question of treatment that he had ever heard. They had gentlemen there with extreme views on both sides; and there had arisen from those gentlemen not only a convergence, but an actual conjunction of opinion as to the point of the value of alcohol in the treatment of fever. In the first place, it was apparently agreed that the patient in fever was like a ship in the storm They could not do very much for the storm; but they could do a great deal in steering the ship in the storm. The main object was to support the life of the patient in passing through the storm of fever. In the next place, when the patient began to fail, and death was threatened, perhaps the best remedy was alcohol. It was also agreed that circumstances arose in the course of the fever, and pointing to failure, perhaps not only was alcohol a successful, but it was the only successful means which they could employ; and that, when they gave alcohol, they must give it with a sparing or with a tentative hand; and so long as certain evidences of disagreement did not arise; so long as the tongue was not dry, as the pulse was not increased; so long as no suppression of urine, and as no increase of delirium occurred; and so long as the patient felt comforted and quiet, they might go on with the idea that they were assisting the patient in arriving at a happy termination of the disease.

Dr. Morell Mackenzie then read an article on

Laryngeal Phthisis,

of which the following is an abstract:—

1. Laryngeal phthisis is due to the presence and subsequent breaking down of tubercles in the mucous and sub-mucous membranes. The tubercles, some very small and some as large as a millet seed, are found imbedded in a reticular structure, filled with small, round lymphoid cells. This tubercular matter is sometimes deposited uniformly through the thickness of the mucous membrane, but much more commonly it is found in the most superficial layer of the mucous membrane, immediately beneath the epithelium. 2. Laryngeal phthisis is essentially a secondary phenomenon, occurring as a sequel to pulmonary phthisis. There is no evidence that any case of *primary* laryngeal phthisis has ever existed. 3. The disease is not due to the corrosive action of the sputa. 4. The disease is much more common among males than females. Out of 500 cases examined by the author during life, 365 were males and 135 females. In a hundred necropsies, there were 73 males and 23 females. 5. The most frequently present symptom of laryngeal phthisis is impairment of the vocal function. In 500 cases the voice was impaired 460 times. Cough was a marked symptom in 427 patients. Dysphagia occurred 151 times. 6. The naked eye appearances of laryngeal phthisis, either during life or after death, cannot be absolutely relied upon, but pale pyriform swellings of the aryepiglottic folds, and a pale, turban-like thickening of the epiglottis, are seldom met with except in laryngeal phthisis. More or less uniform thickening, with marked pallor, of the mucous membrane, and small scattered ulcers, are the characteristic features of the disease. 7. The prognosis is always unfavorable, the ordinary duration of life after the throat symptoms have become troublesome being from twelve to eighteen months. 8. The only treatment which is of any use consists in the employment of palliative remedies. Where there is pain in swallowing, insufflation of morphia gives the greatest amount of relief.

A number of papers were read on

Tracheotomy in Croup.

One of these, by Mr. W. Thompson, of Dublin, gave a short account of six cases in which he had operated, with two successful results. He discussed the subject under two heads: 1. Under

what circumstances ought the operation to be performed? 2. What conditions will tend to insure its success? He expressed his belief in medication in the early stages; but when a membrane was present he believed that the treatment should be by emetics; and failing success, that tracheotomy ought to be performed, provided that urgent symptoms were present—such as the sinking in of the substernal tissues and of the parts at the root of the neck. He regarded the operation as simply relieving an urgent mechanical obstruction, thus preventing the poisoning of the patient by carbonized blood, and giving time for the use of other remedies, if necessary. He advocated the suprathyroid operation, as being quite as efficient as the infrathyroid, while it was less difficult. Steam spray, a full-sized tube, careful nursing, and the spraying of the trachea occasionally with lactic acid solution or lime water, were regarded as important helps to success.

The propriety of the operation in certain cases was generally recognized.

Mr. Corley stated that he regarded the operation as one of the most serious—he did not say the most dangerous—in surgery. Of the dangers, shock was a necessary concomitant; congestion of the lungs or bronchitis from contact of the cold air with the pulmonary mucous membrane, if it existed, was quite avoidable. The immediate and complete oxygenation of the blood which followed a free opening in the trachea, the consequent resumption of the vital functions, and the cessation of the exhaustion and ineffectual struggles for air, justified any risks incurred in performing the operation. As to the proper time for operating, much stress was laid, in the hospital with which he was connected, on substernal sinking in respiration, which showed that the lungs were not descending while the diaphragm was contracting.

In a paper by Dr. E. T. Tibbets, on

The Action of Digitalis,

the author believed that digitalis was strictly a cardiac sedative and a general depressant, and that it did not, as a rule, increase arterial tension. Apart from the experiments and clinical observations previously alluded to, he arrived at the following results: 1. Small doses, *e.g.*, one to two drachms of infusion, three times daily, are quite sufficient to produce nausea and even vomiting. 2. One-sixtieth of a grain of digitaline dropped into the eye produces dilatation of the pupil. 3. Its action in many ways is identical with that of tobacco, aconite, lobelia, etc. 4. No example is recorded of its ever having produced a hard, powerful pulse and general vascular excitement. 5. Its diuretic action is probably due to dilatation and not to contraction of the small vessels. The present modern theory the author believed to be dangerous. The sphygmographic observations made with regard to arterial tension he considered open to many fallacies. As one result of these observations, digitalis had been recommended in fatty degeneration of the heart, which the author regarded as injudicious as the administration of opium to a patient suffering from uræmic drowsiness.

Dr. A. Harkin spoke of the

Treatment of the Hemorrhagic Diathesis.

He observed that in this diathesis, which is characterized by a diminished proportion of fibrin, a soft clot, an absence of the buffy coat, accompanied with a delicacy of structure in the capillaries and minute vessels, a remedy is required that shall increase the fibrin, add to the plasticity and chemico-vital elements of the blood and restore its coagulating power, as well as the contractile action of the capillaries; and thus destroy the dyscrasies, in which a slight wound may lead to excessive hemorrhage, a trifling contusion to extensive extravasation. That this salt, whether given alone or in combination with iron, possesses the very desirable property of controlling the various developments of the hemorrhagic diathesis, and that its persevering administration will neutralize the constitutional taint on which these ailments depend, Dr. Harkin hoped to establish by the relation of satisfactory cases, selected from an experience of its value extending over more than twenty years' observation. He generally ordered the medicine in the form of one ounce of a saturated solution three times daily, one ounce of the salt to a pint of water; and if iron be required, an addition of one drachm of the muriatic tincture to the solution completes the mixture. Administered in this proportion, Dr. Harkin had had the greatest satisfaction in the treatment of epistaxis; in hæmophilia; in hemorrhage from the bowels, from the kidneys, from the lungs, from the stomach; in menorrhagia; in scurvy; and in purpura hemorrhagica.

Dr. Octavius Sturges spoke of

Chorea as a Functional Disorder.

His paper was designed to show, from an examination of the ordinary phenomena of chorea, that the affection in its simple and uncomplicated form is not due to any lesion which is demonstrable anatomically; and that its symptoms are not otherwise to be explained than by reference to the general character of disturbed muscular movement, when the source of such disturbance is, directly or indirectly, a mental impression. This position it was sought to maintain by reference to (1) the age and sex of the patients; (2) the actual character and common association of the affection; and (3) the modifications it undergoes at the various periods of life.

Papers were presented on

Albuminuria.

One by Dr. R. Saundly, on the "Apparent Presence of Albuminuria in Healthy Persons." He thought paraglobulin was sometimes mistaken for albumen.

Dr. C. R. Drysdale read on "Syphilitic Albuminuria." He said that no matter what treatment had been made use of, he had found that, in certain cases of syphilis, a fatal termination occurred by the insidious commencement of nephritis, usually far on in the disease, but occasionally arising precociously, or within a year after infection. The latter was, however, very rare indeed. The morbid anatomy of syphilitic albuminuria may consist of diffuse inflammation of the cellular elements of the kidney, which, as in the case of syphilitic cirrhosis of

the liver, spinal cord, etc., leads to the destruction of the secreting cells, and ultimately to fatty degeneration of the organ. In some cases circumscribed gummy inflammation forms small tumors in the substance of the kidney. The disease usually commences silently, is accompanied by anasarca, and may end in death from asthenia or in coma. The diagnosis is made out by the history of the case, and is often quite clear; but even when the history is indistinct, assistance may be gained by noticing whether there are any scars on the liver after death. Dr. Drysdale gave the clinical history of an acute case of syphilitic nephritis occurring in a young man, aged twenty-eight, with large rupia sores recently cicatrized, and with a short history of infection ten months before. He rapidly sank and died.

Dr. Churton, of Leeds, spoke of

The Perignosis of Patients.

He informed his audience that the word "perignosis" meant knowing about the patient, his circumstances and surroundings, and especially the disordering influences to which he had been exposed, both recently and during his former life. The importance of this knowledge in practice, and the difficulty of obtaining it, were alluded to. The mode of examination was described, and appended to the paper were printed forms used in the Leeds Dispensary.

Editorial Department.

Periscope.

Treatment of Eczema.

The following directions are given by Dr. J. B. Bradbury, in the *Lancet*:—

Cases of acute eczema speedily recover if the patients are placed upon an unstimulating diet, and have soothing applications to the skin. In acute general eczema the alkaline and bran baths are very valuable, and local applications of olive oil and lime water (the *Linimentum calcis* of the Pharmacopœia), or lead lotion. When the disease has somewhat subsided, the internal administration of arsenic and the local application of zinc ointment hasten the cure. In the case of a gentleman I saw in consultation, who was gouty and had albuminuria, colchicum with magnesia quickly removed the malady. These remedies are also very valuable in chronic eczema occurring in persons of a gouty habit. Indeed, in eczema, as in all diseases, the importance of looking for some diathesis cannot be over-estimated. A disease often resists cure till such constitutional vice has been discovered and corrected. A short time ago I cured a gentleman of gouty eczema with liquor potassæ in thirty-minim doses, given with compound infusion of gentian, three times a day.

In chronic eczema of the hands arsenic almost invariably does good, and as a local application, the diluted nitrate of mercury ointment. For eczema of the axillæ, which is frequently accompanied by boils, the internal administration of the perchloride of mercury, and the local application of mercurial ointment, are almost a specific. I have cured two cases of this kind which had resisted all other treatment. The combination of iron with sulphate of magnesia is most valuable in the treatment of eczema in anæmic young women with constipated bowels. The dose of sulphate of iron should be larger than that usually given. I give three- or four-grain doses. In anæmic young men the tincture of perchloride of iron, in at least half-drachm doses, answers better than the sulphate. I quickly cured a medical student of chronic eczema of the legs by this treatment, when other remedies prescribed by a specialist had failed. In chronic eczema of the face an ointment of equal parts of white precipitate ointment, and either zinc or compound subacetate of lead ointment is very useful. Sometimes, especially where the hairy parts are affected, the dilute nitrate of mercury ointment succeeds better. In eczema of the lips a private patient has derived great benefit from an ointment composed of almond oil, yellow beeswax, new honey, and oxide of zinc, a formula which I obtained from a paper by Dr. Durkee, in the *Journal of Cutaneous Medicine*. I have cured two cases of eczema of the nostrils by the application of dilute nitrate of mercury ointment. This ointment is best diluted with vaseline. Preparations of tar are of great use in some cases of chronic local eczema, but English skins are not so tolerant of these remedies as German skins.

Patients subject to chronic eczema should, as a rule, avoid salt meats, soups, sweets, acids, fruits, pastry and raw vegetables.

Eczema in young children is frequently a very troublesome malady, probably owing to the disturbing influence of dentition. In children a few months old, where the disease is syphilitic, I give gray powder night and morning, and apply a mercurial ointment. When the disease has somewhat subsided, I give the syrup of the iodide of iron. The perchloride of mercury has disappointed me in these cases. In non-syphilitic eczema, after correcting any error in diet, and attending to the state of the secretions, I prescribe the ferro-arsenical mixture of Mr. Erasmus Wilson, and apply the zinc ointment, and generally with the happiest results. I have recently cured three cases of eczema of long standing, which had resisted all previous treatment, by this method. It is very important in this, as in all forms of eczema, that the treatment should extend over a considerable time, in some cases six months. In eczema of the scalp, and generally in impetiginous eczema, after the

removal of the scabs by poultices and oil, the local application of the *unguentum hydrargyri cum plumbi* of the Skin Hospital is invaluable. Eczematous children are almost invariably benefited by cod-liver oil.

Treatment of Fistulæ and Scars of the Cheek.

On this subject Mr. Edward Bellamy, F.R.C.S., writes to the *Lancet*—

It is, in the first place, all-important to find out exactly the course taken by the fistula or fistulæ—a matter of considerable difficulty sometimes; and the following classification may have its value in diagnosis: 1. Those opening into the cheek, with a track above the level of the buccal or labial mucous membrane, and which usually discharge saliva only. 2. Those whose track lies below this level, and which discharge pus and muco-purulent fluid and no saliva. 3. A complication of both forms, and which discharge both pus and saliva. With regard to the accurate detection of their course, an ordinary probe frequently gives merely a general idea of the direction, without passing into the offsets. I have always found that a fine filiform bougie, or better still, a fine india-rubber French bougie, is more useful than anything else. After having determined the course, irritating cause, and condition of the fistula, in order to avoid further scar, the dead bone, if there be any, is to be removed by delicate but strong forceps or gouge, and afterward the track should be washed out with a very strong solution of sulphuric acid, which has the effect of completely destroying the fistulous track; or by the introduction of minute crystals of nitrate of silver, until the granulations appear at the orifice, gentle pressure being maintained. A cicatrix, however carefully the treatment be carried out, is sure to remain, unsightly always and often troublesome, appearing as a "pucker" or adhesion to the underlying bone; and with regard to its treatment, I venture to state, from my own experience, that two methods are open to the surgeon, dependent on the extent or strength of these adhesions. The first consists in introducing a fine blunt-pointed tenotome through the tissue of the cicatrix—laminating it, as it were—taking great care to leave it in free communication with the integument adjacent to it; next, to introduce between the split surfaces a thin strip of sheet-lead, which should be kept in, to prevent the adhesion of the surfaces divided by the tenotome. After a few days, the superficial lamina of the cicatrix may be subjected to gentle movement over the lower lamina, which the patient may conduct himself; this prevents adhesion, and renders the tissue pliant and assimilative. This may be termed the "passive movement" of the cicatrix. The second plan, if the former fails—or indeed it may be advisable at first—consists in dissecting away the adherent tissue entirely, vivifying the edges of the cicatrix and bringing them together by means of fine entomological pins, and so gaining a mere linear scar at worst, care being taken, by movement, to prevent permanent adhesion. The great elasticity of the cheek structure permits of this without any deformity resulting as regards expression. Manipulative skill is necessary for success, but results appear so satisfactory that I am inclined to think that, in cases where it is important, for the sake of the patient's looks, operative proceedings should be undertaken, the above suggestions may be of use.

Therapeutical Value of Drug-Smoking in Asthma.

On this subject Dr. R. E. Thompson writes to the *Practitioner*—

The leaves should be procured in good condition, and perfectly fresh; they should then be soaked in a solution of nitre (25 per cent.), and the leaves then dried by gentle heat and powdered. I have made use of the various neurotics in this manner, in asthma, first separately, in order to ascertain the individual value of the remedy, and then in combination, and the experiments have now been carried on for many months, and I am disposed to place them in the following order of merit: opium, stramonium, cannabis indica, conium, lobelia.

The three first on the list appear to be the most potent by fumigation, but when administered in the wet method (if I may use the term) cannabis indica is so uncertain and so apt to produce delirium, especially in women, that I prefer conium, a drug from which I have obtained extremely good results, when administered by the mouth.

With belladonna I could not satisfy myself that any good results were to be obtained by fumigation, and I consider it far inferior to those given above, in whatever way it is administered.

The powder may be used by those patients who are not accustomed, or object, to smoking cigarettes, or it may be added to the tobacco of those who prefer the use of the pipe.

As regards the composition of the powder, I have had good results from gr. ix of stramonium and gr. j of cannabis indica, this being a quantity, which will cover a shilling, sufficient for one fumigation.

But if the patient does not object to smoking I much prefer to administer the remedies in the form described in my previous paper, namely, paper cigarettes impregnated with tinctures, so that the dose may be accurately apportioned.

It will be understood that in suggesting remedies which serve to alleviate the spasmodic dyspnœa of asthma, I do not consider that they constitute a mode of treatment calculated to improve the general condition of the patient, or that they are more than palliatives of an urgent symptom: constitutional treatment by ferruginous tonics and cod-liver oil, or it may be by iodide of potassium or arsenic, must be resorted to, if it be intended to give the asthmatic patient permanent relief from distressing disease. With acute conditions of the disease, with bronchial complications of such a nature as to contra-indicate the use of iron, there is probably no treatment better for a majority of cases than the use of iodide of potassium with stramonium; in many cases of like character I have derived very good results from the administration of hemlock in combination with the hypophosphite of soda, but for the prevention of the disease I know no treatment to compare with iron and cod-liver oil.

But for soothing and diminishing the dyspnœa, neurotics may be used with great effect; and the following combination is that which, up to this time, has given me the best results.

The same form of cigarette is used as described in my former contribution on this subject, and the paper is soaked in the following drugs, according to the recipe here given:—

Extract of opium,	gr. $\frac{1}{64}$
Extract of stramonium,	gr. $\frac{1}{32}$
Tincture of Indian hemp,	♏ $\frac{1}{4}$
Tincture of hemlock,	♏ $1\frac{3}{4}$
Tincture of lobelia,	♏ $1\frac{3}{4}$
Tincture of tobacco,	♏ 9
Oil of anise,	♏ $\frac{1}{8}$
Nitre,	gr. $\frac{1}{4}$.

Or for a sheet of Swedish paper sufficient to make sixty-four cigarettes, the formula may be given thus:—

Tincturæ tabaci,	℥ x
Tincturæ conii,	℥ ij
Tincturæ lobeliæ,	℥ ij
Tincturæ cannabis ind.,	♏ xxxij
Extract. opii,	gr.j
Extract. stramonii,	gr.ij
Olei anisi,	♏ viij
Potassæ nitratis,	gr.xvj
Spir. v. r. ad,	℥ ijss.

This formula, which is a complex one, has only been obtained from repeated experiments, leading step by step to the addition of some effective remedy and omission of less useful ones.

What is Malaria?

The *Practitioner* quotes, on this subject, the recent researches of Professor Klebs and Signor T. Crudeli. They say—

The organisms which, according to our observations, are to be regarded as the true causes of malaria, since they are to be found in the infective liquids obtained by the earth from the air, and by cultivation, as in the bodies of infected animals, belong to the genus *bacillus*. In the soil of malarious regions they are found in the form of numerous spores, which have the power of independent motion, and strongly refract the light. They have an elongated oval figure, and a maximum diameter of 0.95 micro-millimeters. They develop, either within the body or in cultivating apparatus, into long filaments, which at first are homogeneous. Later on, these filaments undergo transverse fission, which converts them into a chain, and in the interior of each link new spores develop. The first formation of these spores is parietal, but finally, almost the whole interior of the link becomes filled with these little bodies. This morphological property seems to correspond to a particular species of bacillus, which we propose to call *Bacillus malariæ*, since we have seen it develop within the bodies of animals infected by malaria.

In regard to the biological properties of this plant, we may mention besides that it requires for its development the presence of free oxygen, and perhaps it belongs to Pasteur's class of *aerobii*. It does not develop in water, but does so in liquids rich in nitrogenous substances, such as solutions of gelatine or albumen, in urine and in liquids of the organism. Its greatest development in the body of infected animals occurs in the spleen and medulla of the bones, which in some of our cases contain long and homogeneous filaments, which measured 0.06–0.084 millimeters in length, and .0006 millimeters in diameter. This circumstance is noteworthy, since it is precisely in these organs that the most characteristic anatomical alterations are to be found, in consequence of grave malarious fevers in man.

The editor of the *Practitioner* adds:—

These researches by Klebs and Tommasi-Crudeli go far to decide the controversy which has long raged regarding the origin and nature of malaria, and to settle this vexed question in favor of malarious poison being a vegetable organism of low origination.

Disease from a Kiss.

Dr. R. L. Payne, of North Carolina, calls attention, in the North Carolina *Medical Journal*, to the danger of conveying disease by kissing. He would do away with this custom. He gives this case and comments:—

A young man came to me with a neglected case of pox. He was already in the secondary stage of the disease, and among other symptoms which presented, had several mucous patches upon his lips and within his mouth.

He had a little cousin, a girl child of sixteen months of age, who was still at its mother's breast. They were very fond of each other, and he was frequently in the habit of fondling and kissing the child.

Of course, I knew nothing of this intimacy, or I should have warned him of the danger. Some weeks after this I was called to visit the child and its mother. I found the little one with enlarged cervical glands, sore mouth, sore eyes, etc., and its mother said to me, after I had prescribed for the child: "Doctor, please look at my nipple, I believe I am going to have cancer of the breast." Her nipple was sore indeed, and her axillary lymphatic glands were enlarged and indurated, not from cancer, however, but from a characteristic chancre.

I treated them all for syphilis, and the good results of the treatment verified my diagnosis. I have seen many similar cases during the last twenty-five years, and many more might be cited from the authorities upon this loathsome disease, but the above are sufficient for my purpose.

Very many other diseases may be conveyed by the act of kissing, and I might go on at length enumerating them, and adducing "confirmations as strong as proof of Holy Writ;" but my object is simply to call attention to the truth which lies in this direction, and to testify most solemnly against a practice so fraught with danger, so pregnant with death!

The act of kissing is never, under any circumstances, indispensable, and the indiscriminate practice is not only unnecessary, but is also foolish, dangerous, and very often insincere.

Ah, yes; many an insidious kiss has been given since the days of Judas! Then, why longer indulge in a custom so empty, so meaningless, but yet so potent for evil?

Catgut as a Vehicle of Infection.

In No. 12, 1879, *Centralblatt für Gynäkologie*, quoted in the Edinburgh *Medical Journal*, Prof. Zweifel, of Erlangen, records a case in which infection resulted from the raising of the edges of an extremely small fistulous opening, which had remained after an operation for transverse obliteration of the vagina. In the case referred to the knife, needle, and hooks were carefully disinfected in a 5 per cent. solution of carbolic acid. The edges were brought together with catgut sutures. Septicæmia and death followed this operation, and the post-mortem examination clearly proved that the death was due to a recent infection starting from the pelvis. The bottle of catgut from which the threads were used on this occasion was then examined, and found to contain bacteria. In other two specimens of catgut examined by Zweifel a countless number of microscopic creatures were seen wriggling between the lamellæ of the catgut. Zweifel considers it as nearly certain that the catgut was the source of infection in the above case, and thinks it absolutely necessary that each bottle of catgut should be subjected to careful microscopical examination before being used. He points out that if the catgut bottle is not securely corked, the carbolic acid gradually evaporates from the oil, more especially if the bottle is kept in a warm room. Zweifel is more inclined to explain the occasional appearance of putrid catgut in this manner, than to believe that it may have been produced from the intestines of putrid animals.

Trigeminal Neuralgia of Long Standing Cured by Aconitia.

Dr. Robert F. Weir, Surgeon to the New York and Roosevelt Hospitals, gives this case in the *Archives of Medicine*, Aug., 1879:—

Peter Derken, aged 38, a German, was first seen April 15, 1879, in consultation with Dr. W. T. Alexander. The patient had had severe neuralgia for eighteen years, affecting principally the distribution of the infra-orbital nerve of the left side of the face, with the paroxysm recurring nearly every minute. Sleep has been obtained by use of chloral and opium.

Eighteen months since the nerve was divided at its point of emergence on the cheek, and half an inch of it removed by Dr. A. B. Mott, of this city. As a result of this operation the pain was absent for three or four months, when it recurred, and it is now more marked in the parotid and temporal regions and along the teeth of the upper jaw. The neuralgia has lately affected the teeth of the lower jaw also on the same side.

Aconitia was advised as worthy of a trial prior to resorting to the removal of the remaining deeper portion of the nerve, and Duquesnel's preparation gr. $\frac{1}{140}$ (obtained at Neergaard's), was exhibited three times a day, which, on the 17th inst., was increased to gr. $\frac{1}{96}$ *ter die*. After the second dose of this strength the patient felt slight coldness over the body, with moderate tingling sensations. No effect on the neuralgia was, however, noticed, and on the 19th four doses of gr. $\frac{1}{96}$ each were given, without any physiological effect, though the pain was made easier, so much so that the patient slept the next night without any anodyne.

April 25th. Has now increased the doses of aconitia to seven per diem, each being gr. $\frac{1}{96}$. No physiological effects have been produced by the remedy, except occasionally a slight chilliness. The amelioration of the pain is most marked. He feels it only moderately in the lower molars in the afternoon. It soon left him entirely.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——In a pamphlet of "Notes of Hospital and Private Practice," Dr. Henry Gibbons, Sr., of San Francisco, gives tersely the most efficient means he has found in the management of a number of common diseases.

——Dr. Nathan Bozeman, of New York, has published, through William Wood & Co., the results of eight cases of ovariotomy, of which seven were successful. He details at length the preliminary and after treatment he prefers, and the steps of the operation.

——Several new medical journals are announced. Among them are a semi-monthly, under the charge of Dr. Dudley, of Chicago, and a quarterly, under that of Dr. C. H. Hughes, of St. Louis. The latter will be entitled "The Alienist and Neurologist," and will be devoted, as its title denotes, to psychiatry and neurology. Dr. Hughes was formerly Superintendent of the Missouri State Lunatic Asylum, and has contributed, from time to time, various valuable articles on his specialty, to current literature.

——With a clear and broad appreciation of the true position of medical men in the community, Dr. D. N. Kinsman, Professor of the Practice of Medicine in the Columbus, Ohio, Medical College, has made a careful original study of the destructive disease among swine, known as "Hog Cholera." He states that $20,000,000 are lost annually by this disease in the United States. From his investigations, he concludes that it is no form of anthrax, nor yet of typhoid fever, but a specific, contagious disease, peculiar to the species. Extensive peritonitis is always present. The essay deserves very general attention.

——Dr. E. Seguin sends an address read before the British Medical Association, at Cork, on his favorite topic, the Metric System. He briefly stated the progress it was making. Following his address, on the proposition of Mr. Ernest Hart, editor of the journal of the Association, a committee was appointed to report on the means

of introducing the metric system in medicine in Great Britain—Dr. Clifford Albutt, of Leeds; Dr. Lauder Brunton, F.R.S.; Dr. Sieveking; Prof. Frazer, Q. U., Edinburgh; Prof. Harvey, University of Aberdeen; Dr. Quain, F.R.S., Chairman of the Pharmacopœia Committee of the General Medical Council, and Mr. Ernest Hart, Chairman of Council.

——"Dermatitis Venenata" is the term applied by Dr. Roswell Park, of Chicago, to the cutaneous eruption caused on many persons by various species of rhus, notably the *R. toxicodendron* and *R. vernix*. His essay, which is quite an exhaustive one, is a reprint from the *Archives of Dermatology*.

——Many persons go through life with a squint that is a deformity, and finally an injury to their visual powers. In a recent reprint Dr. J. J. Chisholm, of Baltimore, urges the advantages, the ease and safety of the operation required to relieve them. He says: From the present status of ophthalmic science I know of no operation in the whole domain of surgery which gives more satisfactory and permanent good results than the scientific operation for squint. In the very large majority of cases, a few weeks after the operation it is impossible to see that any defect in the position of the eyes had ever existed.

——Of all the deaths that occur in civilized countries nearly one-fourth are those of infants less than one year old. Nearly one-half of all deaths are those of children less than five years old. In view of this sad fact the Wisconsin State Board of Health has this summer distributed largely a series of instructions on the care of infants and young children. They are carefully prepared. Among other facts the circular states that the popular idea that the second summer is the most dangerous to the life of the child is fallacious; it grows, doubtless, in part, out of another and dangerous popular idea, that diarrhœa is a natural and almost necessary attendant upon "teething," and that it is wrong to check a diarrhœa which occurs during this process. At the very commencement of any such disorder in children it should be controlled, and this may very often be done by observing the rules given, and without medicine.

BOOK NOTICES.

Transactions of the College of Physicians of Philadelphia. Third series. Volume IV. Philadelphia, Lindsay & Blakiston.

This volume contains the Transactions from the summer of 1877 to the summer of 1879. We have printed in the REPORTER sufficiently full accounts of the papers read before the College, so that we need not recall them here.

The volume is well printed, and can be obtained of Messrs. Lindsay & Blakiston, of this city.

The Student's Guide to the Diseases of Women. By Alfred L. Galabin, M.D., Lecturer at Guy's Hospital. Illustrated. Philadelphia, Lindsay & Blakiston, 1879.

In the compass of 350 small octavo pages the author of this work gives an epitome of what a student will find it most essential to learn about diseases of women. He necessarily omits much, as, for instance, almost nothing is said about gynecological operations, nor about the diseases incident to the pregnant state. It is, in fact, no longer possible to do justice to the subject in so brief a space; but with this disadvantage to contend with, and having in view the wants of students only, Dr. Galabin has succeeded as well as any one could expect him to, exercising good judgment in his selection and treatment of topics.

Physiology and Histology of the Cerebral Convolutions. Also, Poisons of the Intellect. By Charles Richet, A.M., M.D., of Paris. Translated by Edward P. Fowler, M.D. New York, Wm. Wood & Co., 1879. 8vo, pp. 170.

The first of these essays includes a full and minute description of the structure of the cerebral convolutions, their development, physiology, physiological properties and their functions. Numerous illustrations are inserted, to render the text more clear, and there is every indication that both original study and a conscientious use of authorities have been summoned to the aid of the author. This is further shown by a bibliography which is added, but which is by no means complete, and we presume only includes works which have been read by the author.

The second essay is called, on the title page of the book, "Poisons of the Intellect," and at its commencement "Poisons of the Intelligence. These words do not mean the same, and both of them are singularly incorrect and inappropriate. What they refer to is the action of the stimulant narcotics, alcohol, chloroform, haschisch and coffee. It was not worth while to translate this paper. It is trite and superficial, and reads as if it was prepared for the instruction of a village lyceum, rather than the scientific world.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE PRINCIPLES AND PRACTICE OF LITHOTRITY.

The REPORTER of January 11th, 1879, contained a communication from Dr. Reuben A. Vance, of Cincinnati, Ohio, entitled, "The Principles and Practice of Modern Lithotrity, and the Recent Issues by which They are Imperilled;" a paper originally read before the Tri-States Medical Society at Springfield, Illinois, November 12th, 1878, and one which attracted no little attention at the time of its first appearance. In this article Dr. Vance described briefly, but accurately, the changes initiated in the bladder when that organ contains a calculus, and spoke of the necessity for measures looking to the control of the inflammatory action it has excited, as well as for those requisite for the removal of the stone; of the two elements which the problem of removing the stone presents—the one, the stone itself; the other, the state of the bladder. For the success of lithotrity, the irritability of the bladder and the urinary passages must be reduced to the minimum; this is the most important preliminary step to be taken by the surgeon. Next, the general health of the patient is to be improved to the maximum; this measure is also essential. In a word, Dr. Vance says that in the case of a patient suffering from stone, with whom it would be reasonably safe—so far as the other bodily organs aside from the bladder are concerned—to perform any capital operation, no surgeon can properly decide against giving him the relief lithotrity affords, until both these measures have been adopted. A moment's glance at the contra-indications of lithotrity show why these steps should be taken. In general terms, stricture of the urethra, hypertrophy of the prostate, atony or paralysis of the bladder, sacculation or carcinomatous degeneration of the vesical walls, villous tumor of the *bas fond*, and renal disease, are the most serious obstacles to lithotrity. By adding to this list multiple calculi, and calculi too large or too hard to be crushed, we embrace all the special contra-indications to this operation. Now, it is a well known fact, that judicious measures can often increase the calibre of the urethra, reduce swelling of the prostate and restore power to the contractile walls of the bladder; in brief, materially modify or completely remove those contra-indications to lithotrity due to the state of the urinary passages, and indirectly influence to an almost equal degree the objections to that operation which arise from the number, resistance and size of the calculi themselves. Therefore, while the measures adopted for the relief of the patient must vary with the special circumstances of the individual case, yet no one should be denied the advantages of lithotrity until a careful study of the phenomena of the given case show that there are contra-indications, which can neither be modified nor removed, fatal to the success of the operation. "Good surgery and the dictates of humanity," continues Dr. Vance, "pronounce in favor of the painless and safe procedure by which the stone is crushed, and reserve for peculiar and exceptional cases the less tedious and more brilliant operation, in which the bladder is cut open and the stone removed at one sitting, as in lithotomy." Reference is then made to the discussion at the Medico-Chirurgical Society of London, reported

in the *Lancet*, of March 16th, 1878, which followed the reading of Sir Henry Thompson's paper presenting an "Analysis of 500 Cases of Stone in the Male Adult." Sir James Paget said that were he recommencing an active surgical practice, he would begin with lithotomy, and reserve for lithotrity only those few cases in which the calculus could be got rid of in two or three sittings. He further announced that he regarded lithotrity as hardly susceptible of additional improvement, and yet its results were often incomplete and unsatisfactory. Even Sir Henry Thompson partook of the prevailing feeling, and stated that in his last one hundred cases he had been drawing the line more closely, and reverting to lithotrity in a larger proportion of cases. With such statements before him, it is not surprising that Van Buren concludes that "the general tone of the discussion was not very favorable to lithotrity," especially when Thompson finally plead for an extension of the line, so as to include cases "where the stone might be crushed at three or, at most, four sittings," beyond which point "he should mostly prefer to cut." No new objections to the operation were urged as grounds for these views. On the contrary, the strongest points against lithotrity were on account of the cystitis "due to the injury done the mucous membrane by sharp fragments of stone and by continued instrumentation," the atony liable to be developed by it in old people, with a continuation of vesical irritability and phosphatic deposits, and the liability to overlook minute fragments, and the consequent unsatisfactory results. With a more complete exposition of the principles upon which is based the modern operation for crushing and removing calcareous matter from the human bladder than we have outlined, taken in connection with the utterances of the eminent surgeons whose names have been mentioned, Dr. Vance inquires if he is not right in thinking that the new issues thus raised are not calculated to do injustice to lithotrity as a surgical operation, and imperil the operation by which the majority of adults suffering from stone are entitled to look for safe and painless relief? Must the body of the profession the world over, he further remarks, be bound by conclusions derived from the practice of a few illustrious surgeons? May not London specialists enjoy a practice not truly representative, and must the profession resign itself to the statement that lithotrity is only applicable to the comparatively limited class of cases in which the calculus can be crushed "in three or, at most, four sittings?" Dr. Vance then answers these questions, by referring to the great prevalence of Bright's disease in Great Britain, and even on our Atlantic seaboard, as compared with the comparative rarity of that affection in the Mississippi Valley, as an element that would alone suffice to impair the value of an analysis based simply on number and fatality of cases. A second, and far more potent influence in the same direction is the fact that notoriously bad cases, and those generally the most neglected, occur among wealthy men, whose means enable them to employ whatever lithotritist they may chance to want.

A New York surgeon takes occasion to refer to this "new departure" in the operative surgery of the bladder, foreshadowed by the paper of Thompson, and inaugurated by the discussion at the Medico-Chirurgical Society, and (Van Buren, in *Record* of September 28, 1878) grants the validity of the objections, but doubts the necessity of recurring to lithotomy as the only remedy, and asks: "Cannot lithotrity be rendered less imperfect?" To this question he responds, that "there is reason to believe that a discovery has been made by an American surgeon which may take away from lithotrity its chiefest objection, and it may prove that, as an operation, it is susceptible of improvement." Van Buren thinks the evidence adduced by Bigelow goes far toward the demonstration of "a tolerance by the bladder of protracted manipulation which has not been hitherto recognized," and publishes cases sustaining the principle announced by Bigelow. Now Dr. Vance, while disposed to accord a certain amount of value to this method of removing calculi in proper cases, doubts the novelty of Bigelow's proposition, and refers to operations by Civiale and Heurteloup, in which the same principles

are clearly discernible. The author of the editorial in the *Record* of August 16, 1879, gives a good idea of the valuable features in Bigelow's contributions to lithotrity, and traces the growth of the measure from a simple improvement of the appliances for washing the bladder, at a time when he crushed without washing, through his first few operations, in which he both crushed and washed, to the perfection of his plan, and its application to the cases in which he crushed the stone and washed out all the fragments at one operation—lithotrity at a single sitting. Vance claims that Bigelow's plan, instead of being applicable to the vast majority of cases susceptible of relief by lithotrity, is, in fact, applicable to but a small minority of such cases. He furthermore believes that Van Buren's question, "Cannot lithotrity be rendered less imperfect?" is not to be answered in the manner that surgeon imagines. On the contrary, it is by the careful study of individual cases, and the judicious application of certain principles deduced therefrom, that the usefulness of that procedure is to be extended, and lithotrity rendered a painless and successful operation. While Bigelow's plan may do in cases where the stone is small and soft, the bladder free from inflammation, and the passages healthy, yet the patients suffering from stone who present this combination of favorable circumstances are but seldom met with. On the contrary, even if the stone is neither large nor hard, yet the bladder may be involved, the prostate enlarged, the urethra contracted or rendered unduly sensitive; and some complication of this kind is present in the vast majority of cases. In view of this fact Vance claims that the improvement of lithotrity depends upon a combination of many circumstances, and the adoption of measures which may vary with different cases. In order to develop to the utmost its applicability, and render it available for the relief of the largest number of sufferers from stone in the bladder, it is essential that—

1. Preliminary treatment should be adopted every case, for the purpose of—

(*a*) Improving the patient's general health;

(*b*) Removing genito-urinary complications; and

(*c*) Recording the patient's temperature, and determining his susceptibility to remedial agents, especially those which act upon the bladder.

2. In this way the surgeon is supplied with a chart by which to guide his steps during the operation, and furnished means to control vesical irritability, or subdue inflammation, should such complications arise, while

3. The temperature record furnishes him an invaluable guide to the frequency, extent and duration of the crushings.

Two other points—the study of the operation so as to develop its capabilities to the utmost, and the accumulation of experience on the part of the individual operator—were mentioned in this paper, but not dwelt upon to any extent. The three headings above quoted include the points interesting to both surgeon and patient. If a careful attention to the patient's general health, and special measures for the relief of genito-urinary complications, tend to remove a sufferer from stone in the bladder out of a class for which the relief that surgery affords is a dangerous and desperately painful procedure, and into one susceptible of cure by measures that are free from danger and devoid of pain, then, surely, too much attention cannot be devoted to these subjects. Furthermore, if, in addition, a record of the patient's temperature (taken in the rectum every six hours), and a determination of his susceptibility to remedial agents, especially those acting on the bladder, supply the surgeon with a chart, as it were, by which he can guide himself during the critical stages of the operation, and check the earliest manifestations of vesical irritability, or local inflammation, it is hard for one to estimate correctly the influence these simple measures will exert over the future of lithotrity. Finally, if to its other advantages, as a prognostic and therapeutic guide in lithotrity, the thermometer enables the operator to regulate to the best advantage the duration, extent and frequency of the crushings, we can readily believe that the future of patients suffer-

ing from stone will be far more advantageously affected by modifications such as are portrayed by Vance in the paper to which we have been referring, than will ever be brought about by the more radical, and seemingly more popular, measures of the day.

Notes and Comments.

Therapeutical Notes.

CHRYSOPHANIC ACID IN SYPHILIS.

Dr. Reumont, of Aix la Chappelle, recommends this acid in obstinate syphilides of the face and hands. He takes—

℞. Chrysophanic acid, 1 to 2 parts
Ung. petrolei, 10 parts. M.

Sig.—Apply once every day or two days.

It is especially valuable in psoriasis syphilitica. Of course, specific internal treatment is continued.

GYNOCARDIA OIL IN SKIN DISEASE.

The chaulmoogra oil, from the *Gynocardia odorata*, is attracting increased attention for its effect in leprous cases. The following formula has been suggested by Mr. J. Moss as a good and economical one for this ointment:—

℞. Oil gynocardia, 2 parts
Paraffin, 1 "
Ozokerine, 5 " M.

The dose of the powdered seeds is about six grains, and of the oil itself three or four grains may be given. The present price of the oil in London is about ten shillings per pound.

SASSAFRAS OIL IN RHUS POISONING.

A correspondent of the *Druggist's Circular* states that a severe case of poisoning from *Rhus toxicodendron* was successfully treated with an infusion of the bark of the root of sassafras. The person poisoned had eaten the leaves of the rhus, mistaking them for the Virginia creeper, *Ampelopsis quinquefolia*, and, in consequence, severely suffered internally. The patient was bathed with the infusion, and was also made to drink freely of it. From the small number of remedies applicable for an internal poisoning of the kind, the above is of interest.

SUGGESTIONS ON DIPHTHERIA.

A writer in the Boston *Journal of Chemistry* gives the treatment of diphtheria of Dr. Herff, of Hillsboro, Ill., which he qualifies as "eminently successful." It consisted substantially of an emetic (pulv. ipecac. and cupri sulph., equal parts, proportioned to age), followed by—

℞. Potass. chlor., ℥ ij
Syr. rub. idæi, ℥ ij
Aq. pur., ad ℥ vj,

both used as a gargle and administered internally.

Prof. Mosler, of Greifswald (*Berl. Klin. Wochenschrift*, No. 21, 1879), strongly advocates the use of protracted inhalations of the oil distilled from the leaves of Eucalyptus amygdalina and globulus, to arrest the local mischief in diphtheria of the pharynx. He asserts that all the cases in this category which he has so treated have recovered, though admitting that there are "fulminating" cases of diphtheria, in certain epidemics, which resist all treatment.

Quinine for Hypodermic Use.

The following is the preparation preferred in the Hamburg General Hospital:—

℞. Quiniæ muriatis, 20 parts
Acidi muriatici 12 "
Ureæ, 3 "

The salt thus formed is soluble in equal parts of water, and hence large doses can be given by the hypodermic syringe.

The quantity of this 50 per cent. solution injected varied from a half to three syringefuls. The local irritation consequent on the injection was in most cases very slight, and at most consisted in a circumscribed burning pain (which was soon relieved by cold Goulard water), without redness or swelling. Doses of a gram produced in men scarcely any subjective sensations, and the noises in the ear complained of by women and children soon disappeared. The anti-febrile effects were evident and certain, intermittents disappearing after the second or third injection. This form of administration seems especially indicated (1) in those sensitive persons who have an invincible objection to taking quinine by the mouth; (2) when gastric affections coexist; (3) in children; and (4) in hospital and pauper practice, as a much smaller quantity of quinine is required than when it is administered internally.

The Poison of the Toad.

The common garden toad is well known to secrete an acrid and irritating fluid in the large warts on its back; but that this ever produces fatal results has not been believed. Nevertheless, the London *Medical Record* reports the case of a child, of six years old, following a large toad on a hot summer's day, throwing stones at it. Suddenly he felt that the animal had spurted some moisture into his eye. There then set in a slight pain and spasmodic twitching of the slightly injected eye, and two hours after coma,

wavering sight, desire to bite, a dread of food and drink, constipation, abundant urine, great agitation, manifested themselves, followed on the sixth day by sickness, apathy, and a kind of stupor, but with regular pulse. Some days later, having become comparatively quiet, the boy left his bed; his eyes injected, the skin dry, the pulse free from fever. He howled and behaved himself like a madman, sank into imbecility and speechlessness, from which condition he never rallied.

Curare in Hydrophobia.

Dr. Offenburg, of Munster, has lately treated with curare a woman who had been bitten by a mad dog. He did not confine himself to the usual small doses, but injected about two decigrams of curare under her skin in the course of five hours. The patient was in a terrible state, and seemed on the point of being suffocated when the injections were made. After the first injection the convulsion ceased suddenly. This was owing to the power which curare has of paralyzing motion. After a short pause, however, the convulsions began again, and several additional injections had to be made. At last the effects of the curare became so powerful that the patient was in danger of dying of paralysis of the heart and the respiratory muscles, and could only be saved by artificial respiration. She then fell into a state of exhaustion and weakness, from which she recovered after a time, and became quite well.

The Frequency of Conception in Prostitutes.

At a recent discussion of the St. Louis Medical Society, Dr. McPheeters expressed the opinion that prostitutes more frequently conceive than is supposed; and the explanation of its apparent infrequency is that in plying their vocation, after conception, from excessive and promiscuous coition, and in the use of vaginal enemata, and other causes, the ovum passes off at the subsequent menstruation, under the head of menorrhagia.

Dr. Hurt expressed the belief that the explanation made by Dr. McPheeters is the correct one in many instances, but from observations he thought prostitutes are not as susceptible of conception as virtuous females are, for the reason that excessive indulgence and the liability to infectious diseases usually bring about a condition of the canal of the cervix uteri that is calculated to be obstructive to conception. Although the uterus and ovaries may be active, the catamenial periods may be regular, the ovaries may be healthy, yet there is a catarrhal condition of the cervix that is calculated to prevent the ingress of the spermatozoa, and consequently to obstruct the process of fœtation or conception.

In a similar way Dr. Thomas Kennard denied that these women become pregnant and abort so frequently as Dr. McPheeters thinks, and considered his position proven by the remarkable exemption from serious illness among the better class of them, and the good health that most of them enjoy, in spite of the depressing and damaging effect that we would suppose their degraded mode of living would have upon their constitutional vigor.

Periodicity of Malarial Disease.

In a work recently published at Leipzig, entitled *Die Gesundheitsverhaltnisse des Marschlandes*, Dr. Dose shows, from a study of nearly 7000 cases of malarial fever, extending over about a quarter of a century, that in addition to the well-known seasonal variations of that class of diseases, there are other undulations of the line of frequency, each embracing about a five years' period. The observations were made about the southern shores of the Baltic Sea, near Meldorf, by Dr. Michaelsen, a country practitioner.

It would be very interesting to have such a study repeated in this country; and as we have pointed out on a previous occasion, this very large and important class of fevers can only be studied to advantage away from cities, and hence it is to *country practitioners* we must look for the work.

The Poison of Typhoid Fever.

It is needless to say that the nature of the poison which gives rise to typhoid is a vexed and uncertain question. There is an able discussion on the etiology of the disease, by Dr. Robert King, in a late number of the *Medical Times and Gazette*. He winds up rather a long lecture with these words:—

"I am inclined to think that it is not only possible, but even probable, firstly, that the poison of typhoid fever is a soluble, and perhaps volatile body, formed on the ammonia type by the decomposition of albuminous matter derived from inflamed intestine; that it may be, in fact, a sort of animal alkaloid; and, secondly, that in the case to which I have specially directed your attention to-day the poison was most likely generated *de novo* in my own house drain, during the putrefaction of the albuminous stools already

mentioned. I think also that, owing in a great measure to the obstruction existing at the point of junction of this drain with the main sewer, the gaseous products of the decomposition were prevented from escaping into the sewer, and ascending the soil-pipe, were absorbed by the water, which, as I have already indicated, was undoubtedly the medium through which the poison was conveyed." This is not exactly sewer gas, but it is close to it. Dr. King suggests that physicians residing in the country are better situated to study this problem than those in the city, as their cases are more isolated.

Correspondence.

On Salicylic Acid.

Ed. Med. and Surg. Reporter:—

Much has recently appeared in medical periodicals on the alleged almost marvelous powers of salicylic acid.

The accounts that have been given from time to time of its efficacy in the treatment of inflammatory rheumatic fever partake, to a considerable extent, of the marvelous, one writer claiming that during his experience with the drug, in the treatment of over forty cases, the disease did not extend over as many *days* as it formerly did weeks under other methods of treatment. And another that to say it excelled all other methods of treatment would be giving it scanty praise. And in the January number of the *Medical News and Library*, 1878, is given the report of a case complicated with pericarditis and bronchopneumonia, that was relieved (when the patient was apparently dying) by the salicylate of soda, after a fair trial of the alkaline treatment. In the St. Louis *Clinical Record* its value as an external application in burns and scalds is presented, and according to the statements made it meets every indication the physician could desire in the treatment of these distressing accidents. Also, in the treatment of pityriasis capitis it is of great value. Dr. Otto, of St. Petersburg, has found an inhalation of a two per cent. solution of the drug to be an effectual remedy in pertussis. Two different writers in the Medical and Surgical Reporter discovered, almost simultaneously, that in the treatment of malarious fevers salicylic acid possessed great tonic and antiperiodic properties, and some controversy occurred as to their respective claims to priority. But notwithstanding the fact that the price of the salts of Peruvian bark was at the time alarmingly high, it was unaffected by the discovery, except that it continued to advance, at a rate more gratifying to Powers & Weightman than to the great army of Shakers. An injection of a solution of the acid in dysentery has been found to relieve the distressing symptoms of that complaint, and to establish convalescence with gratifying celerity. In the *British Medical Journal*, of recent date, a writer claims to have used it for the last three years with "unvarying success," in the treatment of both mild and severe cases of scarlet fever and diphtheria. Its virtues in typhoid fever have also been set forth with equal vigor. Its wonderful utility in restoring the hair in alopecia was set forth extravagantly in an article I read not long since.

The profession have not, however, been a unit in this unqualified endorsement of its merits. Dr. C. T. Jewett found that a patient to whom he had administered the drug for some time was no longer able to obtain an erection of the penis, and this power was only restored after the remedy had been discontinued some time. A veterinary surgeon put himself on large doses of acid for the cure of rheumatism, and although he did not claim that it prevented stiffness of the joints, it did prevent stiffness in other localities to such an extent that the unfortunate man had no erection for the space of three months. A writer in the *British Medical Journal* stated last summer that fifteen grains *of the pure acid*, used as a snuff daily, would cure hay fever; and a physician in Kentucky innocently duplicated the prescription for one of his patients, who was not copper-lined, with the most unpleasant results. Injury of the teeth and necrosis of the tibia have been ascribed to its use, and the charge is apparently sustained by the fact that the urine is loaded with the calcareous salts of bone when the influence of the drug is obtained.

Dr. Charles H. Hall, of Macon, Ga., claims, in a January number of the *Medical and Surgical Reporter*, 1878, the honor of immortalizing an African by its use. "While undue conservatism is not a virtue," yet still it is a significant fact that the testimony of those men who would be considered authoritative as to the medicinal value of any new drug is generally the last obtained. Alfred Stillé states in his last work, the *National Dispensatory*, that if salicylic acid and its compounds are curative of any disease it is rheumatism; and in a clinical lecture of recent date says that he is personally unacquainted with the effect of the drug in this disease, and has thus far not even been tempted to employ it.

That it is necessary that we should experiment to a certain extent, in order to determine the effect of new remedies, is true, but we should ever bear in mind, while so doing, that the position of the pioneer physician is more enviable than that of the pioneer patient.

Utah, Illinois. Livy Hatchitt, M.D.

Sulphurous Acid as a Disinfectant.

Ed. Med. and Surg. Reporter:—

From my observations and experiments with different chemicals, I find that sulphurous acid will destroy all animaculæ and fermentation if it can be brought in contact with it. It is evident that the disinfectants used on the U. S. steamer "Plymouth" did not have the desired effect of destroying the germ or virus on board of that vessel. I think the reason is very plain why it did not. There was bilge water in the hold of the vessel, and the fumigation for two days, with one hundred pounds of sulphur, was not sufficient to acidulate the water in the hold of the ship, to destroy the germ or virus.

The medical inspectors of the United States Navy, W. T. Hound, T. W. Leach and Charles H. Burbank, say: "We made a careful and thorough inspection of every part of the ship ("Plymouth"), personally, visiting cabin, ward-room, steerage, berth deck, sick bay, store room, shaft alley and bilge, and found them all in a very cleanly condition and free from all offensive odors. The bedding and clothing were aired while we were on board, and appeared to have been well cared for. On the berth deck, from abreast the galley aft, we found very many of the knees, ends of cross timbers, and large portions of the inner planking, in a badly damaged condition. Officers and crew were apparently in excellent health. A few men ill with trifling diseases, and one convalescing from yellow fever, formed the sick list."

The damaged timbers and the bilge water are the places where the disease germ would seek a hiding place. Covered with water and moisture, the fumes of sulphur could not reach the poison. The vessel was in Boston harbor several weeks during last winter, and the weather was very cold, so much so that buckets of water froze on board of the ship. After all the fumigating, cleaning and freezing, as the medical inspectors assert, the vessel was refitted and put to sea during the first days of last March, and after having arrived in the tropics a gale came up, rendering it necessary to close the hatches of the vessel; the motion of the ship in the gale stirred up the bilge water and set the disease germ free in the ship, and the men imbibed the poison by being confined in the infected air of the ship, and hence the breaking out of the disease—yellow fever.

I am of the opinion that if the bilge water and the rotten timbers had been thoroughly saturated with sulphurous acid, there would not have been a return of the fever on board of the Plymouth. My examination and experiments with the microscope on bacteria taken from the vomited matter of a man who was suffering from a malignant malarial fever, during the few warm days of last March, show that it contained great numbers of them, very active, when the temperature was above 90° Fahrenheit. I cut slips out of the shirt that the patient vomited on, and put them in warm water, the water having been previously boiled, in order to destroy any animalculæ that it might contain. After standing a short time I examined the water under the microscope, and found it alive with bacteria.

I tried several chemicals in the water, in order to ascertain what would destroy the life of bacteria. I am happy to say that sulphurous acid and the temperature of boiling water had the desired effect. I have three specimens in my office, corked in vials, which I have kept since the ninth day of last March. I have examined the specimens often since that time, under the microscope, and in the two specimens that contained no sulphurous acid the number has increased threefold; in the specimens to which I added sulphurous acid not one can be found alive.

I have examined these specimens often since that time, during cold weather, and found them motionless, but by holding the vial containing them in the hand, or next to the body, until the vial was warm, and then examining them, the microscope showed very active movements.

Evansville, Ind. W. S. Ross, M.D.

News and Miscellany.

International Quarantine.

At a meeting lately held in London, Eng., of the Association for the Reform and Codification of the Law of Nations, Sir Sherston Baker, Bart., read a paper on International Rules of Quarantine, containing a number of excellent suggestions, which he presented in the form of forty articles. The following brief outline of his suggestions refers to the plague, yellow fever, and cholera: An "international bill of health" to be granted by the local authority of the port of departure to every vessel, and to be delivered up by the vessel at the ultimate port of destination. This bill to be *viséd* at the port of departure by the consul representing the port of destination, in such terms as he shall think fit. A similar *visé* to be required at every port touched at, both from the local authority and from the consul representing the port of destination. This bill of health to be accepted in all ports of the high contracting parties. A foul bill of health, or a case of disease, past or present, on board, or the fact of any port having become infected within a limited time after the departure of a vessel from it, to authorize the local authority of the port of arrival to place the arriving or touching vessel in quarantine, according to a certain scale, containing a maximum and a minimum period of quarantine; it being optional to every State to adopt any period within those limits. Every State to preserve its own municipal quarantine system, except on such points as may nullify or contradict these articles. Measures of disinfection for passengers, crew, and cargo to be required, but in every case to be left to the municipal regulations to supply the details. Lazarets and hospital ships to be provided in sufficient number, and to be regulated according to the best sanitary principles, but again the details to be left to the municipal authority. To avoid the necessity of placing a whole State in quarantine, especially where a State comprises distant colonial possessions, each country to be divided by its own government into territorial divisions, to be termed quarantine "centres." Each State to engage to guard rigidly against any infected "centre," and to place the same in quarantine.

Hypodermic Injection of Morphia.

Dr. H. H. Kane, of New York City, who has for some time past been collecting statistics on the hypodermic injection of morphia, would consider it a great favor if members of the profession who see this, and have had experience with the instrument, will answer the following questions:—

1. What is your usual dose?
2. Do you use it alone or with atropia?
3. What is the largest amount you have ever administered?

4. Have you had inflammation or abscess at the point of puncture?

5. Have you had any deaths or accidents caused by this instrument?

6. Do you know of any cases of opium habit thus contracted?

Where there has been an autopsy (5) please state the fact and the results obtained therefrom. All communications will be considered strictly confidential, the writer's name being used only when he gives his full consent thereto. Address all letters to Dr. H. H. Kane, 366 Bleecker street, New York.

Medical Missionaries.

Dr. J. Kevoe Kian, of Chicago, contradicts the report that young Turkish students sent to America to receive an education qualifying them for missionary work, aim instead at learning medicine, so as to be able to go home and practice profitably. The Turks, the Doctor says, have been sent here for a religious education, though "there are a few young Armenians, members of missionary churches, who, seeing the need of medical men among their people, have come to this country to obtain instruction. The missionaries themselves often speak of this need, and the older missionaries have encouraged these young men in their effort. Three or four of them have studied both medicine and theology, a few only medicine. They have returned to Turkey, and are now laboring as Christian physicians, and are producing an impression which is highly honorable both to their brethren and to this country."

The Cultivation of Cinchona.

In striking contrast to our government, the ruling powers of Holland, England and France have taken the greatest interest in making themselves wholly independent of other nations for their supplies of the cinchona alkaloids and bark. In India the English, in Siam the French, and in Java the Dutch, have appropriated large sums to introduce the best cinchona seeds and establish large nurseries. A cinchona plantation is found to be as good as a gold mine. The net profits of those in Java are about $70.00 per hectare (not quite 2½ acres), and with proper care the plantation will increase in value every year, at a rate greater than the interest of its cost. The Java bark yields from seven to nine per cent. of quinine. It is the *Cinchona calisaya ledgereana*, and is worth nearly double the best South American bark.

Mortality of Cities.

The following are the death rates of some large cities: It appears that Alexandria heads the list, with a mortality of 44 per 1000. After the Egyptian capital comes Breslau, with a death-rate of 41; then Buda Pesth, with 39; New York, 36; St. Petersburg, 35; Berlin and Bombay, 33; Naples, 32; Munich, 31; Brooklyn, 30; Dresden and Madras, 29; the lowest being the Hague, with a death rate of 17 per 1000.

Pharmaceutical Preparations.

THE LOWER ALKALOIDS OF BARK.

It may be taken for granted that, in this country, more attention will have to be paid to the other alkaloids of bark than quinine. We have at various times called attention to "cinchoquinine" as an efficient substitute. Dr. Henry Gibbons, of San Francisco, speaks of it very favorably in his "Notes of Hospital and Private Practice." It is prepared by Billings, Clapp & Co., Boston. In this city the firm of Keasbey & Mattison prepare "dextro-quinine," which Dr. Gibbons mentions as "a very active agent." As these substitutes can be bought for much less than quinine sulphates, their value is evident.

Items.

—Portugal has issued a decree, establishing quarantine against the State of New York and the State of New Jersey. The decree is based on "official information and the report of the Consulting Board of Public Health." The effect of this quarantine is reported by the United States consul at Lisbon to be very oppressive to American vessels entering the ports of Portugal.

—Three medical celebrities met together to consult, at the sick bed of General X. After they go, the General rings for his man-servant: Well, Jacques, you showed those gentlemen out; what did they say?" "Ah, General, they seemed to differ with each other; the big fat one said that they must have a little patience, and at the autopsy—whatever that may be—they would find out what the matter was."

—Some experiments have been made by Dr. B. Joy Jeffries, of Boston, to detect the existence of color blindness among the employes of railroad and steamboat companies. Dr. Jeffries has recently examined some of the employees of the Boston and Lowell Railroad, and his report to the company states that out of ninety-four employes constantly called upon to distinguish lights by their color, two were color-blind and eighteen were below the visual standard.

—An ingenious device is mentioned in the *Veterinary Journal*, by which horses given to biting, rearing, kicking, etc., are rendered inoffensive, and submit peaceably to be groomed and harnessed. To obtain this result a weak current of electricity is passed into the mouth of the horse each time it becomes restive; the will of the animal seems almost annihilated. The current is produced by a small induction machine, the wires of which communicate with the bit of the bridle. In the case of resistance by the horse, the driver has merely to push a button, when a current passes immediately, and the animal becomes docile. The employment of electricity is said to produce a sort of uneasiness or torpor, rather than pain, and is much less barbarous than many taming methods hitherto adopted, such as those which depend on weakening by deprivation of food, on fatigue, etc.

DEATH.

FINLEY.—At his residence, in Philadelphia, September 8th, Dr. Clement A. Finley, ex-Surgeon General of the United States Army, in the 82d year of his age.

TAMAR INDIEN,

A laxative, refreshing, and medicated Fruit Lozenge, agreeable to take, and never causing irritation. Its physiological action assures the immediate relief and effectual cure of

CONSTIPATION, CEREBRAL CONGESTION, HEADACHE, INDIGESTION, BILE, HEMORRHOIDS, etc., etc., by augmenting the peristaltic movement of the intestines, without producing undue secretion of the liquids. Unlike pills and the usual purgatives, it does not predispose to intestinal sluggishness, and the same dose always produces the same effect, that is to say, never needs increasing. These properties render "Tamar" invaluable to the weak and debilitated, and especially to ladies previous and subsequent to their accouchement. It is recommended by the most eminent Physicians of Paris; notably Drs. BELIN and TARDIEU, who prescribe it constantly for the above complaints, and with most marked success.

Prepared by **E. GRILLON,** Pharmacien de lère classe, 27 Rue Rambuteau, Paris. To be had of all respectable Chemists throughout the world.

PEPTODYN.

The New Digestive is a combination of the whole of the Digestive Secretions—Pepsine, Pancreatine, Diastase, etc.,

Forming an invaluable remedy in the treatment of all forms of Dyspepsia, and diseases arising from imperfect nutrition.

N. B.—*The success of this Remedy has led to several imitations of it,* which consist largely of Milk Sugar, and, as compared with Peptodyn, are of little or no real value as digestive agents.

SAVORY & MOORE, 143 New Bond Street, London.

PARIS, 1867. Prize Medal.

1868. Silver Medal.

1872. Gold Medal.

1873, VIENNA Medal of Merit

BOUDAULT'S PEPSINE

IN POWDER, also WINE, ELIXIR, SYRUP, PILLS, AND LOZENGES OF PEPSINE.

Since the introduction of Pepsine by Boudault in 1854, **BOUDAULT'S PEPSINE HAS BEEN, AND IS STILL CONSIDERED, THE MOST RELIABLE,** as is attested by the awards it has received at the Exhibitions of 1867, 1868, 1872, 1873, and in 1876 at the Centennial Exposition in Philadelphia.

IT IS THE ONLY PEPSINE USED IN THE PARIS HOSPITALS.

Careful tests will enable any one to satisfy himself that **BOUDAULT'S PEPSINE HAS A DIGESTIVE POWER AT LEAST DOUBLE** that of the best Pepsines in the market, and that it is really the cheapest.

It is Sold in 1 ounce, 8 ounce, and 16 ounce Bottles.

Beware of so-called French Pepsines bearing fictitious names, and prescribe Boudault's only.

BLANCARD'S PILLS

OF UNCHANGEABLE IODIDE OF IRON.

Blancard's Pills of Iodide of Iron are so scrupulously prepared, and so well made, that none other have acquired a so well deserved favor among physicians and pharmaceutists. Each pill, containing one grain of proto-iodide of iron, is covered with finely pulverized iron, and covered with balsam of tolu. Dose, two to six pills a day. The genuine have a *reactive silver seal* attached to the lower part of the cork, and a green label on the wrapper, bearing the fac-simile of the signature of

Blancard

Pharmacien, No. 40 Rue Bonaparte, Paris.

without which none are genuine.

BEWARE OF IMITATIONS.

E. FOUCERA & CO., Agents,

NEW YORK.

NEW REMEDIES.

FLUID EXTRACTS.

Coto Bark.—From BOLIVIA. Almost a specific in acute and chronic diarrhœa, cholera, cholera morbus, etc.

Cascara Sagrada.—(**Rhamnus Purshiana.**) From the PACIFIC SLOPE. A certain remedy for habitual constipation; and very useful in all cases where a laxative or cathartic is indicated. Beware of the fluid extracts of spurious varieties of this bark.

Folia Carobæ.—From BRAZIL. A powerful alterative, which exerts a marked curative action in syphilis, scrofula and kindred disorders.

Rhus Aromatica.—A remedy in diabetes, and other diseases of the genito-urinary organs.

Damiana.—(**Turnera Aphrodisiaca.**) From MEXICO. The best known aphrodisiac. Of great value in impotence, spermatorrhœa, and loss of sexual appetite.

Boldo.—(**Peumus Boldo.**) From CHILI. The new tonic. Very useful in dyspepsia, hepatic torpor, yellow fever, etc.

Berberis Aquifolium.—From CALIFORNIA. Has marked alterative and tonic powers, and has been used with extraordinary success in salt rheum, psoriasis, eczema, scrofula and syphilis.

Black Haw.—(**Viburnum Prunifolium.**) From the UNITED STATES. Employed to prevent abortion and miscarriage.

Grindelia Robusta.—From CALIFORNIA. A valuable curative agent in asthma and diseases of the air passages.

Grindelia Squarrosa.—From CALIFORNIA. Anti-malarial. Used in enlarged spleen and other malarial diseases.

Cereus Bonplandii.—(**Cereus Grandiflorus and Cereus McDonaldii.**) From MEXICO. Heart sedatives. Very useful in controlling functional and organic disturbances of the heart.

Kaki.—(**Diospyros Kaki.**) From JAPAN. Peculiar action on the mucous surfaces. Useful in mucous dyspepsia, typhoid fever, etc.

Cercis Canadensis.—Indigenous. A positive remedy in chronic diarrhœa, dysentery, etc.

Jaborandi (diaphoretic). **Guarana** (sick headache). **Fucus Vesiculosus** (anti-fat).
Bearsfoot (enlarged spleen). **Coca** (nervous stimulant). **Kava Kava** (Gonorrhœa).
Eucalyptus Globulus (antiseptic and anti-malarial). **Yerba Santa** (coughs).
Yerba Reuma (catarrh). **Wood Betony** (dyspepsia). **Ustilago Maidis** (oxytocic).
Penthorum Sedoides (catarrh). **Soap Tree Bark** (tooth wash).

CRUDE DRUGS.

Goa Powder (ringworm and diseases of the skin). **Gurjun Balsam** (a substitute for Copaiba).
Alstonia Constricta (a substitute for Calisaya).

SUGAR-COATED GRANULES.

Calcium Sulphide 1-10 gr. (for the cure of boils and carbuncles).

Our limited space prevents our describing in detail the history and application of each remedy, but to those interested in NEW REMEDIES, we will say, that we can furnish interesting information relative to the above new drugs.

PARKE, DAVIS & CO.,

DETROIT, - MICHIGAN.

Our New Remedies can be procured of the Drug Trade throughout the United States. By specifying **"P., D. & Co.'s"** in all cases, you will ensure reliable preparations of the **true drugs.**

W. H. SCHIEFFELIN & CO.'S

SOLUBLE

Pills and Granules.

UNEQUALED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

1. The best materials are used in their manufacture.
2. No article required by a formula is omitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.

Our list of Pills and Granules embraces those made according to the formulæ of the U. S. Pharmacopœia; also most of those in common use among the profession.

Trade supplied in Philadelphia by

ROBERT SHOEMAKER & CO.

COMPRESSED
Coated Tablets.

I ask the attention of physicians to the above new and elegant form of preparing medicines.

The discovery and successful application of the process of compression to the coating of medicines with a thin envelope of chocolate, sugar, etc., thereby avoiding the application of heat and the employment of tenacious pill-mass excipients, marks a great advance in elegant pharmacy, and fully meets the requirements of a refined taste.

The process is available for nearly every medicine, including, besides those articles adapted to pill and powder form, several others, such as Chloral Hydrate, Iodide and Bromide of Potassium and Pepsin; while for Quinine and other bitter and nauseous remedies it is unsurpassed.

Owing to their small bulk, thinness and lenticular shape, they may be easily swallowed, and are readily taken even by children.

All officinal and standard unofficinal formulæ for pills, etc., are put up in this new form.

The prices will correspond as near as possible to the best made pills and granules in the market.

Chocolate coating is used regularly, unless the sugar is ordered.

Send for samples.

R. & J. BECK,

MANUFACTURING OPTICIANS,

1016 CHESTNUT STREET,

PHILADELPHIA,

Beg to call the attention of physicians and students to the following novelties recently introduced by them:—

Beck's New National Microscope, Monocular,	$ 75.00
Beck's New National Microscope, Binocular,	100.00
Beck's Economic Microscope, Monocular,	35.00
Beck's Improved Economic Microscope, Monocular,	50.00
Beck's Improved Economic Microscope, Binocular,	80.00
Beck's New Histological and Dissecting Microscope,	25.00
Beck's New Model Dissecting Microscope,	15.00
Beck's New Volute Turn Table, self-centering for all slides,	7.00
Mr. Walmsley's New Freezing Microtome, complete, with Atomizer,	20.00
Beck's New Clinical Thermometers, with indestructible index and ineffaceable scale.	
Dr. Seiler's Section Knife and Carrier,	12.00
Dr. Woodward's Diatom Prism, mounted,	1.50

The above instruments, together with every article used by the microscopist, will be found fully illustrated and described in our catalogue of 144 pages; mailed free to any address.

R. & J. BECK,

ON ATMOSPHERIC THERAPEUTICS.

BY T. S. SOZINSKEY, M.D., PH.D.,

Of Philadelphia.

In that fragmentary work of Bacon, "New Atlantis," in which, after the manner of More's "Utopia," features of an ideal State are described, it is said: "We have certain chambers, which we call chambers of health, where we qualify the air as we think good and proper for the cure of divers diseases and the preservation of health." These words embody an important idea, which has not been as yet duly appreciated, which two hundred and fifty years have not sufficed to properly develop and carry into application. There are plenty of hospitals, but really no "chambers of health;" these have still to come; and such institutions have in them, I believe, the promise of great usefulness to suffering humanity.

Everybody knows that the presence of air is absolutely essential to life; that in absence of a due supply of it death speedily ensues. This being granted, the question arises, whether or not the state as well as the supply of the air is of vital importance. As I have fully shown in articles published in this journal, the atmospheric variations of a seasonal nature have much to do with the mortality as a whole; and that the relation between such and other changes in the air and many diseases is very intimate, I hope to show in the future. It is a familiar fact that air which contains much carbonic acid cannot be breathed without immediately disastrous results, and sulphureted hydrogen and other gases are quite as injurious. But after making full allowance for the effects of these and all agents, including electricity, which may be present in more or less abundance in the air, one must turn to the temperature, humidity, pressure, and light or sunshine, in which to discover the leading causes of the variations in the death-rate at different seasons of the year at any place. Of course, if it be granted that a relation between the state of the atmosphere and the death-rate can be easily traced, it follows that a relation between it and the sickness-rate exists. This relation is doubtless still more apparent than the other, but I need only refer to it here. Then, there is every reason to believe that the variation in the death-rates of different places is largely due to a difference in the state of the air, or, in other words, to climatic differences. This is so obvious that I will not dwell on it.

Now, if the state of the atmosphere, as regards temperature, humidity, pressure and light, is potent in causing disease and death, in spite of the ordinary efforts that are made to counteract it, the question arises, Is it not possible to completely control it? Well, it must be acknowledged that on a large scale it is impossible to control it in any essential respect, at least immediately. Gradual change of climate, through extensive agricultural and other operations, can be induced, but of this it is not to my purpose to speak. On a small scale, however, it is possible, and not very difficult either, to regulate the state of the air at pleasure, excepting, perhaps, in the matter of pressure. In a house or close inclosure of any size, the temperature, humidity and light, at any rate, can be

easily modified; these can be raised or lowered to any reasonable degree.

Seeing, then, that it is possible to modify, in nearly every respect and to almost any degree, the state of the atmosphere, on a scale sufficiently large, it is certainly a little surprising that no "chambers of health" have been established for "the preservation of health." Why is it that there is not in the whole country a single establishment where the air is regulated throughout the year with scientific precision? Hundreds of young lives might be saved every year, in any of our large cities, if there were halls at hand with air properly reduced in temperature, in which delicate children could be kept for a few weeks, or it may be days, in the heat of summer.

But it is of "chambers of health" for "the cure of divers diseases," that I especially desire to speak. These are still more important than ones for "the preservation of health." When disease is present, the state of the air should be considered as a matter of the utmost concern; for it may greatly influence the patient's condition for good or ill. That comparatively little attention is given to it is only too apparent to any one who pays a visit to any of the leading hospitals. Considerable care is taken to keep the air free from extraneous matters, through ventilation and otherwise, but little more is done excepting in winter, when it is heated. In summer it is not cooled, and at no time is any particular attention given to its humidity. I am not aware that a hygrometer is used in any hospital in Philadelphia. And yet Dr. Edward Smith feels justified in saying, in his book on "Health," that "health, and even life, depend upon this quality of dryness or moisture of the atmosphere which is breathed or which surrounds us." Here I may remark that what is commonly called the atmosphere might be more properly called the atmospheres; for there is no union between the oxygen and the nitrogen or the moisture, or between any two elements present. The old idea that water is supported by "adhering to air," as Franklin expresses it, has been obsolete since Dalton promulgated, in his "Meteorological Observations and Essays" (1793), the true doctrine, namely, that it, as well as all elastic fluids and gases, is independent and self-supporting. We live in an atmosphere of aqueous vapor, which varies constantly in density. As elsewhere pointed out, this is the great medium of heat, the element which regulates the temperature. And it exerts control over the temperature of living organisms as well as the air. How this is so I may briefly explain. Well, just as the relative humidity is high or low, so will the moisture that is in the body tend to evaporate slowly or quickly; and as every one probably knows, the evaporation of water requires a great deal of heat. In this way heat is always being abstracted from the system; for evaporation is going on constantly, from its entire surface, and also from the lungs. The air which issues from the lungs is always heavily loaded with moisture, always of a relative humidity, according to Espy and other meteorologists, of between ninety and ninety-five. In this connection it must be remembered that the tension or pressure of the aqueous vapor atmosphere, as well as the relative humidity, exercises an influence over the temperature of the body. Thus, when the actual amount of vapor in the air breathed is small, and the relative humidity is low, which is often the case in cold weather, not only does this vapor and the accompanying air absorb heat from the blood, but a large amount of additional vapor being required to highly saturate the inspired air, a corresponding amount of heat must be abstracted. The amount of heat drawn from the system in this way may be imagined when it is borne in mind that the capacity of air for moisture is more than quadrupled through a rise of temperature from the freezing point (32°) to 80°, a point considerably below that of expired air at all times. Living in a cold, dry atmosphere is stimulating for a while, but exhaustion speedily comes on, unless counteracted by nutritive activity. The consumption of oxygen and other chemical changes are involved, heat promoting them and cold retarding them.

But bad as it is, that scarcely any attempt is made in institutions devoted to sanatory purposes to regulate the state of the air, generally, it is worse that little or nothing is done to modify it to suit each patient, according to his disease and its stage. Persons of age and temperament the most diverse, and with diseases entirely unlike, are put in the same ward, in the best of hospitals. Beside a patient with a raging fever may be seen another that is convalescent, or one in the acute stage of inflammation of the lungs, side by side with one recovering from that serious disease. Is this as it should be? Is the practice not to a degree as irrational, not to say criminal, as it would be to put all on the same diet and medicine? It certainly seems a little absurd to administer medicinal agents with no great certainty of getting the desired results from them, while the immersing medium, so to speak, is for the most part entirely neglected. The air is in a sense a

composite bath, and its state should be regulated in like manner. The physicians of antiquity were more advanced in this regard than we are to-day. Thus, in speaking of the treatment of phrenitis, Aretæus says: "The patient should be placed in a house of moderate size and mild temperature; in a warm situation in winter, and in one that is cool and humid in summer; in spring and autumn to be regulated according to the season." One looks in vain for so explicit directions in our modern works on practical medicine.

Of course, no one will understand me to mean that the physician can or should rely on aerial medication alone in the treatment of any disease; I do not wish to do more than place it among the most useful resources of his art.

A very important bearing of the state of the air in the treatment of disease may be referred to, and that is, its modifying influence on the effects of medicines. It is patent to common sense that a change in the forces which act on the organism from without, which antagonize those that are acting within, must increase or diminish, or otherwise affect, the action of any agent administered. This is a familiar fact to the habitual users of stimulants, and in all cases the difference between the effects of any medicinal substance, say when the air is warm and moist and when it is cold and dry, must be very considerable. Here is a matter which receives little or no attention, a field of observation to which therapeutists seem to be oblivious to a lamentable degree. Careful study in this direction would assuredly tend to the advancement of the science and art of healing.

Ever since the study of the chemical composition of the atmosphere began to be pursued with success there have been loud proclamations of the discovery of infallible means of curing disease. When the nature of oxygen was demonstrated, there were, and, indeed, still are, persons of the belief that with it nearly all diseases might be successfully combated. It cannot be denied but that it is an agent which plays a vital part in the animal economy, and it is, I believe, a powerful, and when properly administered in suitable cases, an excellent remedy; but it is by no means a cure-all. Proper ventilation insures the presence of very nearly the normal proportion of it in the air at all times and everywhere. Ozone, too, which is not a constant, and consequently not, properly speaking, a normal constituent of the air, is extolled by quacks as a remedy of sovereign virtue in manifold ailments. It has stimulating properties, but it is as an aerial purifier that it is of much interest to the physician. It certainly might be utilized in hospital wards and elsewhere to great advantage. Both it and oxygen might be added to the air of any apartment, just the same as moisture, and under many circumstances, doubtless, to good purpose.

What is called the climatic treatment of disease, which has been assuming more and more importance ever since the publication of Sir James Clark's book on "The Sanative Influence of Climate" (1841), is similar in principle to the treatment under consideration; but notwithstanding modern facilities for traveling, it is far more difficult to carry it out. One advantage of moving to a different place of abode is that the influence of a lesser or greater degree of pressure can be brought to bear on the system, and another is the change of scene, which is often very beneficial.

Special modifications of the air for sanatory purposes have been recommended from time to time, for a long while, in fact, from the days of Hippocrates. Sydenham made use of cold air in the treatment of smallpox, and from its value in that disease was led to advise it in all fevers, in the presence of great morbid activity. It is not a little amusing to read, in a periodical for the present month, that a German *savant* has just discovered this method of treatment. This expedient is, of course, somewhat similar in principle to the application of cold water in the treatment of fevers, which has been so much practiced of late; the immediate effect of either is to reduce the temperature and in turn the excessive vital activity, of which it is the result. To the philosophical as well as practical physician last named should be largely ascribed the credit of introducing the use of cold in these diseases. This is generally overlooked by modern writers. In Dr. Hosack's "Practice of Physic," published fifty years ago, the subject is ably discussed, including the cold water treatment of yellow fever. But it should not be forgotten that the ancients knew a great deal about the medical uses of water. Hippocrates recommended the bath in various forms in sundry diseases, and Pliny tells us that it was to the Roman common people a sort of panacea.

Vapor, hot air and sun baths are being used more and more for numerous diseases. Through them it is possible to at once produce profound changes, more or less permanent in character, on the system. Of medicated vapor and hot air baths, matters which are beyond my province, I may remark that the effects of the vapor and heat are generally overlooked in summing up the

results from them, and of the administration of medicines by inhalation a similar remark applies. In this way it is easy to make the mistake of according to a thing virtues which it does not possess. Students of medical history will remember how that eccentric but popular physician, Dr. Thomas Beddoes, dwells, in his "Observations on a Modified Atmosphere in Consumptive Cases" (1801), on the virtues of "a heated atmosphere impregnated with the exhalations of the cow-house." Of this curious treatment he remarks, "I have long been in the habit of recommending it." Among the patients treated by him in this way, was Mrs. Finch, the daughter of Dr. Priestly. There is something in this "cure" which recalls the method spoken of in the Middle Ages as being one of the most infallible for insuring perpetual youth, namely, to live constantly in the air respired by a company of girls.

In London, some time ago, the establishment of an extensive institution for the prevention and cure of disease through the regulation of the state of the air was agitated, but, I think, nothing came of it. In St. George's Hall, in Liverpool, washed air, that is warmed in winter and cooled in summer, is mechanically injected. When it is thought proper the degree of humidity is lessened through absorbents and increased through a steam jet. Several years ago an article entitled "Life Under Glass" appeared in the *Atlantic Monthly*, written by Mr. Geo. A. Shove, and which later (1874) was enlarged and placed before the public in book form, in which the erection and maintenance of a building for sanatory purposes were advocated. The scheme suggested was similar to the London one just referred to, and did not partake of the "blue glass" principle of procedure, which has no scientific standing as yet. In one of the hospitals of New York city there is a sort of hygienic hall, in which convalescents are placed to bring them under the influence of the sunshine. It is located under the glass-covered roof, and some attention is paid to the condition of the air as well as the light.

From these brief notes it will be apparent to the reader that the time is approaching when the scientific regulation of the state of the air with a view to the prevention and cure of disease will be systematically practiced. The measure being possible, and having in it flattering possibilities, it is to be hoped that it will be introduced soon, and extensively, too.

In conclusion, I would ask all physicians who are in possession of any facts as to the effects of different degrees of temperature, humidity, etc., of the air, on any disease at its various stages, to be kind enough to communicate with me. In this way I hope to gain much practical information, which I will embody in the studies of the relation of the meteorology to individual diseases, on which I am engaged.

2210 *Fairmount avenue.*

CLINICAL STUDIES OF INEBRIETY—HINTS OF THE PATHOLOGY.

BY T. D. CROTHERS, M.D.,
Superintendent of Walnut Hill, Hartford, Ct.

The pathology of inebriety has never been clearly studied. The very excellent papers of Drs. Burr and Parrish were largely preliminary, opening up the way for other observers, and suggesting what would require long years of observation to confirm. Some English and French writers have hinted at many different theories, but in the absence of correct data, these have only served as corner stones for enthusiastic writers to build speculations, either for or against the question of disease.

Of late, Dr. G. M. Beard, of New York, has pointed out many pathological phases of inebriety in connection with other diseases, particularly in his studies of neurasthenia, which indicate a vast chain of hidden forces, culminating in inebriety, guided by laws as certain as those which govern any other disease.

Dr. Jewell, of Chicago, in a valuable lecture entitled, "On Certain Forms of Morbid Sensibility" (published in the American Clinical Lectures, volume II), has suggested clearly many conditions of the nervous system which precede inebriety, notably seen in the cases we have studied in previous numbers of the REPORTER.

We present some of these facts, with their signification, which are worthy of a more extended study.

Inebriates have always a defective condition of brain and nerve organization, either inherited or acquired.

There is also present a lesion of nutrition, consisting of a loss of balance between the waste and repair going on in the system.

The waste is not repaired, either from want of rest or proper nutritive materials.

In one case the constant excitement and strain upon the nerves are not repaired by sleep from day to day; the tension is kept up without relief or rest.

When the nutritive materials are wanting, in

both quality and quantity, the blood is poor, and lacks in building-up material; when this passes a certain limit the nerves suffer, and make it manifest in various forms of neurosis.

This loss of proper balance of the nerve force is frequently inherited. Children of inebriates and those of nearly all forms of mental disease have this entailment. It is one of the most prominent marks of the sins of the fathers visited on the second and third generation.

This may also come from actual disease, direct, as from alcohol in continuous or toxical doses, and indirect, as the result of some diseased conditions, such as acute fevers, that are rapidly wasting, etc.

In some of these cases there is present a morbid restlessness of the nervous system, a tendency to exhaust itself by seeking excitement, and centres of great mental activity, with no regard to the effects on the body. They seem to be laboring under a kind of delirium of both mental and physical activity, manifest in a constant desire to be moving about, and disinclination to rest any length of time, with intense pleasure in excitement, either of labor or amusement.

In these cases nervous exhaustion is always present, and also the tendency to alcoholism.

In other cases there is from the first a reckless disregard of nutrition and the purpose and object of eating. The greatest irregularities in both quality and quantity of food is an every day experience; the result is an impoverished body and nervous system, always wanting in vigor and integrity of action.

When these conditions are the result of alcohol, or the entailments of disease, the loss of brain and nerve power, with the general failure of the higher nerve centres, and capacity for endurance, etc., will be apparent in any ordinary observation.

It is a fact worth noting, that in all the cases of exhaustion traced to inheritance and alcohol, there is present a want of consciousness of the real danger; they never seem to realize the loss of power, and have no sense of the danger and difficulty of restoration. With this exhaustion come delusions and mental perversions; also great instability of both brain and physical force.

The seat of this disturbance is evidently in the nerve centres, and is either a condition of paralysis or exalted sensibility. In one case the capacity for receiving or giving impressions is diminished, and the mental action following is defective and irregular, the wants of the system are never realized, and when they are, the action is disproportionate, and the coördination is irregular and uncertain. For instance, the demands for food and rest, to relieve this condition, will bear no comparison to the actual wants.

In the other case, of exalted sensibility, there is present an unstable, sensitive condition, which responds to every impression, reflex or direct, and may be noted in all forms of neuralgia and functional nervous disturbance.

This condition is often psychical and cannot be clearly defined, but always gives way to rest and improved nutrition.

Alcohol taken to intoxication, in nearly all cases, is the exciting cause of these varied conditions of nerve exhaustion. The toxic action of this drug may either paralyze these nerve centres, controlling nutrition, breaking up the coördinating power of repair, or may develop a constant tendency to exhaustion, from increased sensibility and irritability to every impression.

There can be no question that inebriety springs from disturbances in the nutrition of the system, dating from the first toxic action of alcohol.

The following case is given as a supplement to many others which have been published in the Reporter:—

J., aged twenty-four, a lawyer, in good health, temperate and of healthy parentage, was intoxicated for the first time, on brandy. He recovered and was strictly temperate from this time on, for five years, when he began to drink, for some imaginary disorder, and soon became an inebriate. A careful study of his history revealed the fact that he had complained of weariness and inability to endure severe mental labor, his memory was not as good, and he was more nervous and excitable, and he had a capricious appetite and temper, all of which grew steadily worse. He attributed these symptoms to a fall he received at the time of intoxication; his friends affirmed the fall to be of a very trifling character, and in no way to account for the symptoms which followed.

Here there was evidently a profound disturbance of the nerve centres presiding over or regulating the repair and waste of the system. The food taken after this event did not build up as formerly, and the rest and repair of the nerves was imperfect.

Dr. Beard has pointed out many conditions of general nervous exhaustion (denominated neurasthenia), which are often present in inebriety, generally before the use of alcohol is noticed, and always after. It seems to follow the destructive metamorphosis of alcohol in all cases, although not generally recognized.

Conditions of neurasthenia following inebriety

are sometimes manifest in painful emotional states, exalted fears and alarm at imaginary evils, dread of sudden death or loss of property, insult of friends, treachery and ingratitude of family, etc. These conditions may be driven away by alcohol, and are often of the nature of delusions, which the patient in part realizes, and resorts to alcohol to quell ; or they follow the action of alcohol on the brain, from which the patient is more or less oblivious after.

Not unfrequently a painful susceptibility to sound and light is present, both before and after inebriety is developed. This is prominent in conditions of excessive nervousness, seen in those of a decided neurotic tendency, often subject to marked exacerbations, in many cases owing to the weather and conditions of surrounding. As in mania and dementia, changes of character and habits are often noticed, always after inebriety has been developed, and in some cases before. These are hints of nerve exhaustion and debility. Psychical depression and conditions of melancholy, which apparently have no clear and positive cause, come and go with more or less uncertainty.

After inebriety has developed, a confusing combination of motor, psychical, and sensory symptoms appear, from a careful study suggesting the region of the brain most affected, opening up many problems of cerebral localizations, which are to be determined by future pathological studies.

The study of the etiology of inebriety is constantly confirming these hints of its pathology.

The following typical cases are presented as indicating the vastness of the field upon which there is little or no literature :—

Inebriety from Nervous Strain and Exhaustion.

A lawyer, aged 34 years; temperate, and of healthy ancestry, living a very quiet life, was unexpectedly elected to a responsible office. He worked with great energy, and was subject to severe mental strain and excitement. After an attack of fever, which seemed to be more from exhaustion than any specific cause, he began to drink freely, and a few months later was turned out of office for inebriety. From his wife it was ascertained that for months before this attack of fever he would work far into the night, and only sleep three or four hours, usually eating with great irregularity. This resulted in profound exhaustion of the nervous system, which found in alcohol a relief. The mental strain and want of sleep were the exciting causes, and the alcohol taken precipitated this condition, and developed both perversions and degenerations of the nerve centres.

Inebriety from Bad Nutrition.

A merchant, aged 29 years, of healthy, temperate living, became a convert to the doctrine that all disease originated in over eating. Accordingly he began to neglect to eat at proper times and places. For days he would eat but once, and often then of food wanting in quality. A year later he began to use beer and crackers, and finally found wine and brandy to be most agreeable. From this to the excessive use of alcohol was but a step, and he was sent to an inebriate asylum, a chronic inebriate and much debilitated, a year after.

The impoverished system, suffering from excessive waste and imperfect repair, manifested itself in conditions of depression, which demanded relief. When alcohol meets this condition the craving is almost irresistible, and inebriety follows as a necessity.

Inebriety from Want of Rest.

A mechanic, of thirty-five years of age, perfectly temperate and in good health, became a night watchman in a large factory, and worked half of the day in addition, for over a year. He became anæmic and complained of persistent neuralgia and dyspepsia. For this he found relief in bitters. Then beer and alcoholic compounds were used, and finally he drank regularly, and to intoxication. He was brought to an inebriate asylum, and after a year's rest regained perfect command over himself, and is now doing well, and a sober, healthy man.

Continuous loss of sleep and proper rest, to both nervous and physical system, developed into inebriety most naturally.

These cases are not uncommon, but are rarely traced to any physical condition, and they illustrate clearly the intimate relation between general nervous and physical exhaustion and inebriety.

In our experience the exhaustion from want of rest and mental strain is the most common cause of inebriety. The use of alcohol in all cases rapidly causes this, with other conditions of degeneration. The nutrition and building up of the body is also interfered with.

From these facts the following general conclusions may be summarized :—

1. Pathologically, in most cases of inebriety there is present a defective condition of brain and nerve organization.

2. This condition is often a lesion of nutrition, consisting of a loss of balance between the waste and repair going on in the system.

3. Every condition which interferes with the

proper repair and rest of the body predisposes to this disorder. The use of alcohol in such cases is always attended with more or less danger.

TYMPANITES, METEORISM OR FLATULENCY.

BY G. W. GARRISON, M.D.,

Of Utica, Ohio.

Read before the Licking Co., Ohio, Medical Society, at its regular Meeting.

The three words above given are all of similar signification, but they are names applied in our text books to a functional or organic derangement of the alimentary tube. Speaking pathologically, we most generally find no diseased condition of any of the mucous follicles or any structural change going on in the primæ viæ. In fact, when flatulency occurs, we regard it most generally as a symptom or sequence of some other morbid action, or else from a hypersecretion from the mucous follicles of the intestines, or the result of certain ingesta causing gas to be thrown off within the alimentary tube. Some of the diseases which this troublesome annoyance seems to accompany are typhoid fever, dysentery, and various irritable nervous affections, etc. While these are only a few of the ailments in which we may have tympanites to contend with, I wish more particularly to call attention to the fact that in some acute diseases of but a few days' or weeks' duration we will find gas accumulating within the bowels, and by neglecting to notice it, and prescribe in time, from its constant pressure, the bowel will become over-distended, and even rupture, in case there should be ulceration, as there oftentimes is in typhoid conditions or dysenteries, etc. Hence, the importance of relieving as speedily as possible such an uncomfortable, as well as hurtful agency going on in the system. You all have, doubtless, examined many cases where the abdominal walls were distended, and heard the patients complain of such a pressure or fullness, as though they would burst; it matters but little what disease your patient is laboring under, there is one thing certain, you must be very careful to relieve as speedily as possible the meteorism, or else you will be of meagre help, to say the least, in remedying any other pathological condition. If this flatulency is not promptly attended to you will soon have more on your hands than you thought of, in the way of complications multiplied; for instance, nervous irritation, supplanted by brain and spinal congestion, and various other things that time and space will not justify to enumerate, but your patient will pass from your hands into that of the undertakers, whose votaries you should try, by all possible means, not to enhance. Promptness and quick perception should characterize all of our professional undertakings, and relieving the little things as we go along, pass nothing by with a glancing or indifferent look, but search for the root of the disease, and then apply the remedy in time.

It might be well to say, in this connection, whenever you see such complications arising, instruct your patient and nurse the importance of passing the wind off and preventing its accumulation, if possible. Hence, the great desideratum at this particular juncture is to forbid visitors seeing the patient, as they may be suffering great inconvenience, as well as running considerable risk, in withholding the escape of gas from the bowels. So it is also important, should your patient be a female, to have none but her sex in the room; and the same is true of males, unless in either case it should be the wife or husband. I would not insist that the patient should strain or make any rude exertion to pass wind, but if it requires only a slight exertion to obtain the desired purpose it should be enjoined.

Treatment.—In the management of tympanites intestinalis two objects are indicated: First, evacuation of the gas, and secondly, the prevention of its re-accumulation. The first proposition has been met by passing a tube up the rectum beyond the sigmoid flexure. A male rubber catheter will answer the purpose if you have nothing else. There are cases, however, this will not relieve, more particularly those suffering from obstinate constipation, or from gas within the small intestines. By administering a cathartic, with some turpentine in it, and a carminative, a great quantity of gas will pass off; then the most feasible plan to put into practice is to bandage the bowels with a good strong cloth bandage, snugly applied from the ensiform cartilage to the crest of the ileum, to be tightened when it becomes loosened. You might use topical application to the bowels before applying the bandage, such as equal parts of camphor, hog's lard and turpentine, and over this oiled silk, and then the bandage. The philosophy of this treatment is apparent at once; you support the muscular walls of the intestine, and exert a uniform pressure upon the gaseous accumulation, causing the wind to pass off by its natural channel, and prevent rupturing the bowels, in case of ulceration or paralysis, from over-distention. In a number of instances you will cause the bowels to move when laxatives and cathartics have

failed; at least this has been my experience. Again, in distention of the bowels of children, when they are suffering with diarrhœa or greenish stools, and the bowels become tympanitic, a nicely adjusted flannel bandage, reaching from the chest to the pelvis, is a great relief to these little sufferers. I venture the assertion, whenever you resort to the bandage in cases of meteorism, your patient will have it continued right along, because of its support and the relief obtained.

Secondly. To remedy this gaseous secretion or fermentation going on in the intestines, we must regulate the patient's diet. Forbid fruits, and allow but little, if any, farinaceous food. Use nitrogenous diet, with milk, eggs, oysters, etc., and medicinally such carminatives and laxatives as suit the case.

I might add more to this production, but as I believe brevity is the spice and life of all such assemblies, I will bring my paper to a close by saying what led me to write upon this subject more particularly was the great relief I have given patients suffering with flatus by bandaging the bowels.

Hospital Reports.

GOOD SAMARITAN HOSPITAL, CINCINNATI.

CLINIC OF JAS. T. WHITTAKER, M.D.,

Professor of Theory and Practice of Medicine, Medical College of Ohio.

REPORTED BY A. H. KELCH.

Yellow Fever.

Gentlemen:—I bring before you to-day a case of yellow fever. It is the last of a series of cases imported from Memphis, all the rest of which have fortunately recovered and left the house. We have had the opportunity of seeing these cases this year, because of the early flight of the inhabitants from infected cities. Our cases all came to us in the stage of incubation. None of them even thought themselves sick until after their arrival. The house physician, Dr. Kelsey, will read us the history of this case.

History.—Georgie N., aged 8 years; English; father living; mother dead, of phthisis. Resided in Memphis up to the outbreak of the epidemic of yellow fever. She left home perfectly well, with the remaining members of the family—father and four sisters (three of whom have since had yellow fever), reaching Cincinnati July 21st. Six days after reaching the city she was attacked with high fever, on the third day of which she was sent by the health officer from a hotel to the hospital.

She is a delicate child, pale and prostrated by the disease; a general yellowish tint manifests itself with the pallor. She vomits everything given to her, and has great tenderness over the stomach. She does not answer questions put to her; is pseudo-somnolent and apathetic. The bowels are loose. The temperature 103°.

You will observe, gentlemen, in this short story, nothing peculiar nor pathognomonic of any one disease. The sudden fever, the profound prostration, the vomiting and epigastric tenderness, are symptoms common to all the infectious diseases. Two quite characteristic symptoms of all these diseases, and especially of this one, do not seem to have been present in any marked degree, viz., the frontal and lumbar pain. But even if they had been present, they could not have been more marked than in cases of variola. The icteroid hue of the skin, which has given the name to the disease in every land and language, is not peculiar to yellow fever. Three of our cases never had it at all. It occurs just as markedly in bad cases of typhus, in malarial fevers and septic diseases. It occurs in all these diseases, because dependent upon the same cause—upon dissolution of the red corpuscles and liberation of the hematine. That is, the jaundice is hematogenous. It has long since been known to be not hepatogenous, because the stools show no deficiency of bile. They are not clay colored, nor do autopsies reveal in yellow fever closure of the bile ducts nor other cause of retention.

So yellow fever is one of the acute infectious diseases, marked by poisoning and more or less destruction of the blood.

Before we proceed with the clinical study of this case, I repeat to you that we have this case here simply because it was brought here. That is, yellow fever does not, and never did, arise in Cincinnati. Nor does yellow fever develop anywhere, originally, in our country. This disease is indigenous to the West Indies, where the natural conditions for its life continually exist. The first ones are imported to us, for the most part, at our southern ports, and at these places the disease may live over seasons and years, until subjected to sufficient cold. Then it dies out and must be reimported anew. Now, although the cold of last winter was sufficiently intense to have killed the germs of the disease nearly everywhere in our country, we have melancholy proof of their survival in Memphis, throughout the whole of the winter, in its reappearance this present year. A uniform temperature of at least 72° F. is necessary to the life of the germ of yellow fever, but even when the season may be much colder than that, the materials containing the germs of the disease may escape exposure to it, and it thus survives over years.

We do not hesitate to take these cases into our wards, because this form of infectious disease is not contagious. No instance is on record where the disease was contracted from the body of a patient sick of it. We say of this disease, therefore, that, although intensely infectious, it is not contagious. That is, the germs of the disease do not multiply in the body, and are not irradiated from it to others. Yellow fever is, in this region, like malaria and cerebro-spinal meningitis. It is

a miasmatic and not a contagious disease. The germs causative of it are in the air; they attach themselves to things and not to persons. Baggage, bedding and bilge-water are the favorite habitats of yellow fever germs. They do not enter the blood, or at least if they do, they do not remain in it, as such. They produce in it changes, and these changes produce certain symptoms, to which we give the name yellow fever. We will, therefore, never find in the blood, in the black vomit, or in any of the juices or discharges of a body sick with it, anything peculiar to the disease—any microscopic parasites, for instance. We do not look to find them, any more than we would look to find splinters in the blood of a man who had been struck with a club. Hence, a miasmatic is very different from a contagious disease. In some forms of infectious disease we have already found, and in others we expect to find, in the body, characteristic germs. Germs which multiply in the body are given off from the body in the exhalations from the skin, as in the exanthemata; in the discharges, as in typhoid fever, dysentery and cholera; these are the contagious diseases proper. But yellow fever does not belong to this class. The germs are not given off from the body, because they are not in it.

One other point of interest deserves mention, because of the general misunderstanding regarding it. We do not owe our immunity to yellow fever on account of our elevation above the level of the sea. You may have seen it stated that yellow fever does not ascend higher than four hundred feet. Now, if this were true we should have nothing to fear, for that is the level upon which we stand, our suburbs being about two hundred feet higher still. But the truth is, yellow fever has climbed to a height of ten times four hundred feet, viz.: four thousand feet above the level of the sea. Newcastle, Jamaica, is about four thousand feet high, and here the disease has prevailed epidemically. Yellow fever will spread wherever it is carried, provided it finds a congenial temperature. We owe our escape, not to elevation, but to quarantine, and not to quarantine extended to persons, but to things.

We have had in the case of this little girl all the prominent symptoms of yellow fever save one. Fever we have had, with all its concomitants; we have had a heavy-coated tongue, nausea and vomiting, tenderness of the stomach, and a yellowish hue of the skin and mucous membranes. Then we have had also, a most essential point in differential diagnosis, absence of any enlargement of the spleen. You observe now that the splenic region is covered by gastric tympanites, and neither before nor behind, above nor below, do we elicit splenic dullness. Enlargement of the spleen attends most of the forms of infectious disease, notably typhoid and malarial fevers, but is absent, as a rule, in yellow fever. The symptom that has made itself conspicuous by its absence, is the black vomit. The white vomit (of mucus) and the yellow vomit (of bile) we have had in this, and in all our cases, but in none were the attacks so grave as to lead to paralysis of the vessels and such complete dissolution of the blood as to permit the escape of it into the viscera. Black vomit (blood) is a fatal sign. It is true, that Alvarenga reports forty recoveries out of one hundred and seventy-eight cases of black vomit observed by him in the great epidemic of Lisbon, but no one before nor since has made this observation. Louis saw it absent in fatal cases, treated at Gibraltar, in only a single case. But it is true that many cases die in the so-called fontage forms before the period of black vomit, and before even the period of discoloration of the skin. These patients die from the direct effects of the poisoned blood upon the nervous system, die as they die after the ingestion or introduction of a virulent chemical or animal poison into the stomach or blood.

Were it not for the fact of the prevalence of an epidemic we should often be led astray in differential diagnosis. Even the presence of albumen in the urine, a very constant sign in bad cases, absent in the patient before us, would not help us much, for such albuminuria is also common to all the grave forms of infectious disease. Fortunately, we have in the thermometric range most valuable and quite characteristic proofs of the form with which we have to deal. The typical temperature of each form of acute infectious disease is peculiar to itself alone. Yellow fever forms no exception to the rule. I show you upon the board the range observed in this case. Unfortunately we lack the records of the first two days. We are informed, however, that the temperature of the second day was as high as 106°. This is a characteristic elevation. The temperature is highest on the second day of the disease, and the height which it here attains gives us some indication of the gravity of the case. On the third day had already begun the second characteristic feature, viz.: the remission. By the fourth day the temperature fell to 101°. Then ensued the exacerbation, the column went up to 105°, to be followed by a sharp descent, with a critical sweat, to nearly the normal grade, where it usually remains. But this child was exceedingly delicate, as is, indeed, plainly visible still. Here is now written in plain characters the struggle which ensued. Eighteen days had passed away before the temperature finally fell to the normal degree, and then the fair prospect of recovery became suddenly marred by a congestion of the lungs, a threatening pneumonia, as evidenced by the sudden rise of temperature to 103°, which was fortunately aborted, however, by a round dose of the bromide of quinia. Since this time we have had to deal with the tedious convalescence that mars even a milder than average case of the disease.

The treatment of this case has been *nil* throughout; cracked ice, milk and lime water, some koumiss, wine whey and ice cream have been the only remedies, excepting an occasional dose of the infusion of digitalis when the urine was unusually scant. The crop of furuncles still present upon the face and extremities appeared also in two other cases in the house. They are looked upon as favorable signs, like the herpes of pneumonia, and are not pathognomonic in any way, of even acute infectious disease, to say nothing of its form.

Medical Societies.

McCALL'S FERRY UNION MEDICAL ASSOCIATION.

Reported for the Medical and Surgical Reporter, by W. N. Baynton, M.D.

The "McCall's Ferry Union Medical Association" is an organization intended to meet the social requirements of physicians, and in which purely professional matters are to a great extent excluded.

This Association owes its origin to the desire of the Lancaster Co. Medical Society to bring together, at some convenient point, the physicians of the remoter districts of the county, and also those of the surrounding counties, for mutual benefit and improvement, and the incidents of its origin, concisely stated, are as follows: Some certain advantages would be secured by a social and non-professional assemblage of the physicians of the lower Susquehanna Valley, which are not presented in a strictly professional meeting, or in the meetings of the several county societies, and it was, therefore, suggested that an invitation from the Lancaster County Medical Society be extended to the physicians of the above-mentioned region, to hold a union meeting at McCall's Ferry, which suggestion was acted upon, and the meeting took place Sept. 4th, 1878.

Representatives, about sixty in number, were present from Cumberland, Dauphin, Franklin, Lancaster and York counties; from Philadelphia, and from Cecil and Harford counties, Md. The meeting was a success in every particular, and the visitors were loud in their praises of the peculiarly wild beauty of the valley and river.

Under the supervision of Mr. Elias Fry, the proprietor of the hotel at McCall's Ferry, and his "gude" wife, an excellent repast was served, and ample justice was done to that part of the proceedings.

The election of officers for the ensuing year (1879) resulted as follows: President, Dr. Alex. Craig, of Columbia; Secretary, Dr. S. S. Rouse, of York; Executive Committee and Committee of Arrangements, Drs. Orth, Montgomery, Dale, Hanna and Deaver.

Then, after having had "a feast of reason and a flow of soul," the Association adjourned to meet at the same place on Aug. 28th, 1879.

The second annual meeting was duly held at the appointed time and place, and in point of numbers largely exceeded the first meeting, as about one hundred and forty persons were present; a goodly number of these were the wives and families of physicians, and invited guests. Chester, Delaware and Lebanon counties were represented, in addition to the delegates from the counties already named.

An informal reception was held in the parlors of the Fry Mansion in the morning, and a hearty welcome was extended to all by the President, who advised them to make the most of the day's opportunities, to throw off all cold and formal rules of etiquette, and enjoy themselves as one medical family; after which they dispersed for the time, to stroll about the places of interest in the neighborhood, some to use the rod and line, some to gather ferns and mosses, some to amuse themselves over games of different kinds, while others gathered in little knots to form new acquaintances, renew old associations, or discuss matters scientific.

At about twelve o'clock the large party sat down to one of Fry's excellent dinners, and after the banquet was finished the various modes of recreation were resumed until the hour of 3 P.M., when the whole assemblage again gathered in the large upper room of Fry's new building, to hold the formal meeting of the day. The exercises opened with the address of the President, whose remarks, though brief, were timely and beautiful. Next in order came the proposing of toasts, which were responded to in an exceedingly happy manner. Dr. W. S. Roland, of York, answered to "Our Meeting" in an exceedingly happy manner, which we would like to give entire, but space forbids. Dr. J. L. Ziegler, of Mount Joy (President of Lancaster County Medical Society), in his usual gallant style, eulogized "Our Friends, the Ladies," closing his remarks with a protest against the education of ladies as physicians. He advised that one of the best ways to keep them out of the profession was for the unmarried doctors to marry them as soon as they showed a weakness for the profession. He thought that any unmarried physician present who could not at next year's reunion bring along his wife, or present his credentials as "duly engaged," ought to forfeit his membership in the Association. The toast, "Our Fraternal Union," was happily responded to by Dr. W. Stump Forwood, of Darlington, Md., who gave his experience in the building up of the county society of which he is a member. "Our Invited Guests," were humorously and eloquently accounted for by one of them, Rev. John McCoy, of Columbia, who, though not yet a doctor (of divinity), is "hale fellow well met." Dr. Robert Bromwell, of Port Deposit, Md., responded to "Maryland, My Maryland," in a courteous and patriotic address, expressing his sincere pleasure at the hospitalities experienced from their Pennsylvania brethren by those who came thither from beyond the Dixie line. Dr. John L. Atlee, Sr., of Lancaster, responded to "Our Sires," giving short biographical sketches of those physicians who flourished before the great majority of those present were born. Dr. S. B. Kieffer, of Carlisle, spoke, in the felicitous style which always characterizes his public addresses, on "Pennsylvania, the Old Keystone," and concluded his remarks by reciting, in his inimitable manner, the story of "Hans Breitman's Party." Dr. A. Sheller, of Mount Joy, pronounced a most sweeping anathema against tobacco, and its use in any form, and thus ended the literary exercises of the day.

After the toasts the necessary business of the Association was transacted, and the following names presented as the officers elect for the ensuing year: President, Dr. John L. Atlee; Vice Presidents, Drs. Robert Bromwell and H. L. Orth; Secretary and Treasurer, Dr. S. J. Rouse. An Executive Committee will be appointed and announced hereafter.

The next meeting of the Association will be held in Lancaster, and it is probable that the

title will be changed to "The Medical Association of the Lower Susquehanna Valley."

Altogether the day was one of unalloyed pleasure, and will be remembered gratefully by those who participated therein, and we hope that each successive reunion may exceed its predecessor in pleasure and profit, and that the praiseworthy objects aimed at by these earnest men may be fully realized.

Periscope.

The Thermo-cautery and Therm-antidote.

In the *Transactions* of the Medical and Chirurgical Faculty of Md., Dr. H. P. C. Wilson has an article on the use of the thermo-cautery. He says—

We have succeeded in devising an instrument which will thoroughly protect the vagina, and all the soft parts about the vulva, from the evil effects of heat in the use of Paquelin's cautery. In operations with this instrument in any deep cavity (as the rectum, mouth, and abdomen), all the parts adjacent to the point of operation will be perfectly safe against the injurious effects of heat.

This instrument, for want of a better name, we shall call the Thermantidote, in contradistinction to the thermo-cauter. It is a hollow cylinder, of sufficient size to allow the shafts of Paquelin's knives to slip easily into it. It is made of German silver, 5½ inches in length. On its upper surface, for its whole length, is a fenestrum of one-fourth of an inch. This fenestrum is necessary to allow the insertion of a curved knife. He adds the following rules as cautions in its use:—

1. The benzine bottle should never be more than two-thirds full. If too full, the slightest tilt of the bottle would cause the benzine to flow down the tube attached to the cauter; and patient, operator and assistants might be set on fire. Or a little extra air forced into the bottle when too full might lift the benzine into the tube by atmospheric pressure, and cause the same accident.

2. The benzine bottle should never be hung to the operator's clothing, or placed in his pocket. If so attached to his person, he, in the act of bending forward, might tilt the bottle, so as to cause a like accident, although very little benzine was in use.

3. The benzine bottle should be held *securely*, in the left hand of a trained assistant, and the rubber bag for heating the knife in the right hand of the same assistant. This assistant, under no circumstances, should be allowed to leave his post for any other work. His only duty is to take care of the benzine, and watch closely the point of the knife, so as to keep it at the proper temperature.

4. The blade of the knife should never be heated too hot. A dull red heat is best, and this redness should never extend above one-third the blade.

5. If the knife is too hot, we cut no better, lose more blood, and are in danger of bending and injuring the blade, and of burning up the platinum gauze within the blade, thus rendering the knife worthless. This latter accident has once happened to me.

6. When we are done using a knife, it should be heated a little extra hot, and while so, quickly separated from the wooden handle. By doing so, no carbon deposit will take place in the knife, and it will be in perfect order for future use.

7. Because of the injudicious heating of the knife, and destruction of the platinum gauze, or clogging of the same with carbonaceous deposit, we are sometimes unable to heat the knife to the operating point. This is very embarrassing, and can be avoided by a little care on the part of the assistant.

8. Every case of Paquelin's thermo-cautery should contain a small metallic brush, with which to cleanse the blade of all burning tissue which adheres to it, with each incision. This clogging of the blade impedes its proper heating. The duty of an assistant is to remove such tissue as it accumulates.

9. In all operations with the thermo-cautery within the vagina four assistants are essential; one to give chloroform, one to work the cautery, one to hand instruments and hold the knife, when the operator desires to be relieved of it, and a fourth to hold Sim's speculum—the only one fit for use in all uterine surgery.

The Treatment of Excitement.

At the close of an article on the treatment of nervous and mental excitement of various kinds, Dr. J. A. Campbell gives, in the *Lancet*, a summary, as follows:—

That in excitement sedative treatment during the day is at times necessary, to render patients manageable. I, however, think that when used for any length of time the patient remains somewhat longer in a stupid or mentally clouded state after the excitement passes off.

That in acutely excited patients, where exercise does not cause sleep at night, it is well to induce it artificially, so as to prevent injury to health from exhaustion; but this form of treatment should only be used for short periods.

That I have found chloral a most certain sleep producer, and harmless.

That with excitement and sleeplessness in chronic patients it is at times necessary, for the quiet of an asylum, to give sleep producers, but the necessity may be much diminished by open-air exercise and employment.

That careful, frequently repeated feeding is as

necessary in the treatment of excitement as in that of any other acute and exhausting disease; that its neglect may induce dementia.

That in the vast majority of cases of acute excitement prolonged exercise in the open air does away with the necessity for sedative treatment or the use of sleep producers, and in a great measure obviates recourse to seclusion, but involves extra supervision and more attendants.

That, after a six years' use of bromide of potassium in epilepsy, I am in a position to corroborate the evidence of others as to its efficacy in the treatment of epilepsy, by reducing the number of fits and allaying the irritability almost always concomitant with epilepsy. The arranging the dose to suit the case, and at intervals examining the patient, as in any other form of treatment, must not be overlooked.

That the morning shower bath is an important auxiliary in the treatment of excitement in the young of both sexes.

That in some cases, where excitement appears due to ovarian irritation, blistering over the ovaries appears to do good, and that this subject is worthy of attention.

The Necessity for Cheap Doctors.

In an address published in the *British Medical Journal*, Dr. R. L. Bowles makes some remarks of general applicability. He says—

We are apt to forget, in our wailings for medical reform, that it is by no means the duty of the legislature to take up the cause of the doctors, and to give them various forms of protection; on the contrary, a statesman should, and would, doubtless, as a rule, see it to be his duty to do the greatest good for the greatest numbers; and it is on this ground that I take leave to differ from the general, almost universal, cry of raising the standard of medical education to a uniform height. I do not see what is to happen to the impecunious, the lower class of tradespeople, to the artisans, and to all those laboring but independent classes above the region of the charity seekers and indigent paupers. It is quite clear that our highly educated and aspiring young practitioners who have had the means of spending five or six years at the hospitals and schools in acquiring their medical knowledge will not descend to accept such fees as these classes are able to afford; and consequently they will be driven to consult quacks and prescribing chemists, or to sacrifice their independence by availing themselves of medical charity. Now, to drive such a large section of the community to spend their money outside the pale of the profession is simply to deprive the profession of a very large amount of income which would, if we gave the opportunity, flow naturally into its coffers.

Even in my own experience, there has existed the (what would now be called) old-fashioned apothecary, the very man who, in my opinion, administered in the best possible way to the medical and surgical requirements of that section of society just now referred to. Some of these we have most of us known personally; men who had open surgeries, where man and maid might have a tooth pulled out for a shilling, or a splinter removed, or an abscess opened for a proportionate fee, or where a mother might have some teething powders for her baby, and ask for some liver powders for her little Johnny; where, in short, all people might have their petty ailments dealt with in a satisfactory manner, and in the cheapest and readiest method. These surgeries were similar to the out-patient room of the hospital or dispensary, only the patients retained their independence on retiring, and left something behind them for the doctor to live upon. In some of our manufacturing towns of the north a few still exist. I have in my mind one gentleman who has prescribed literally for hundreds daily, and has his dispensers at hand to make up quickly what is ordered; the shilling, more or even less, is paid for the medicines, and the doctor becomes rich and enjoys a fine country house, with carriages, horses, and their attendant luxuries. Another case, too, I know of in a coal and mining district, where a firm of three partners prescribe in a similar way, and have a clerk to see fair play; a basin stands on the office table, and the pitmen and their families put in what they can afford. These gentlemen are all of high character, and two of them I know to be exceptionally talented both in medical and surgical cases.

It is open to question whether provident dispensaries can ever take the place of the open surgeries; the public does not like to be bound by societies in such a personal matter as health, nor does it feel so independent in its choice of a doctor.

I regret that these valuable men are fast dying out. From their enormous field of observation they became quick sighted in detecting diseases, and had a ready way of dealing with them; and although they could not, perhaps, so profoundly investigate an obscure case, they would often, in the lesser things in physic (which after all form the chief part of our practice), be wiser and more trustworthy than the theoretically and highly educated man of more recent date.

Venereal Warts and their Treatment.

In a work on Skin Diseases, lately published in Germany, Dr. Behrend gives a remarkably good account of venereal warts, and notices the variety first described by Hauck, called subcutaneous or endofollicular wart. These form within the sebaceous gland, obstructing its opening, and hindering the discharge of its secretion. There arises in consequence a whitish-yellow prominence of the size of a barleycorn, from which, when squeezed, there escapes first a little plug of sebum, and then follows the small wart-like growth. Kaposi regards these formations as identical in nature with so-called molluscum contagiosum, and as only differing in form; he proposes the name of molluscum verrucosum for them. In treating venereal warts, Behrend rightly observes that it is not sufficient to remove them by the knife or scissors; to check their tendency to regeneration the base so exposed must be touched with nitrate of silver or liq. ferri perchloridi. He also expresses himself favorably of

savine, used as an ointment, composed of three parts of powdered savine to twenty of glycerine of starch. This is thickly applied night and morning, by means of a brush. But while dealing with the local treatment of these warts, our author entirely omits to notice the most important part of all, viz., the curative treatment by astringent injections of the irritating discharge, which, in the female at least, both causes and maintains them. Without attention to this, all mere local medication affords but temporary relief. And to neglect of this is due a circumstance noted by him, that warts which had existed during pregnancy are apt to recur after parturition.

Iodine to the Os Uteri in Vomiting of Pregnancy.

The following case is reported in the Cincinnati *Lancet and Observer*, by D. M. Wick, M.D., of New Hartford, Iowa:—

On the 23d of last May I was called to see Mrs. H., suffering with excessive vomiting in her first pregnancy, throwing up a black grumous liquid every twenty or thirty minutes. She had been troubled thus some six weeks—four of which she was not able to leave her bed—vomiting quite all the nourishment taken, and consequently was very much emaciated and weak. Believing that her previous physician (who is a very intelligent and successful practitioner) had exhausted the whole list of remedies *per os*, I concluded to try iodine to the os. Using the speculum and a camel-hair brush, I painted the os with tinct. of iodine. In ten or fifteen minutes slight contractions of the womb came on and continued, at intervals, four or five hours. Ordering, for nourishment, beef tea and brandy, administered by the rectum, and to slake the thirst small pieces of ice swallowed entire, I took my leave.

Next day I found, to my great surprise and pleasure, that my patient had vomited but once or twice since the application. She rested well during the night, and in a few days was able to retain in her stomach such nourishment as was given her. She made a rapid recovery and had no more nausea and vomiting.

The Salicylates in Rheumatism.

Dr. John F. Alexander writes to the Louisville *Medical News*—

I have treated a number of cases of acute rheumatism in the last two years with salicylate of soda—which I prefer to the acid, being more pleasant to take—and can conscientiously say that it has done all I expected of it. I always give alkalies with the soda if patients suffer much pain; give Dover's powder every four hours; see that the bowels are freely moved at least every other day. When I use Dover's powder I usually give the two drugs together to an adult—ten grains of soda to six grains of powder every four hours. Now, it might be claimed that the alkalies with Dover's powder would control the disease alone without the soda. So it might if the attack was not a severe one. But I claim for salicylate that it will not only assist in curing the disease, but will mitigate the symptoms to such an extent that the severity of the attack will be arrested; and can say further that since using this remedy I have met with no cardiac disturbance following acute rheumatism, which difficulty I often met prior to its use.

For chronic rheumatism I do not claim much benefit; yet in one case of a young lady of nineteen, who had been troubled with attacks of chronic rheumatism which lasted for several weeks, I was called to see her at the commencement of one of these attacks; and, by giving ten grains of salicylate of soda every four hours, succeeded in arresting the attack in six days. I have also given it in other cases of chronic rheumatism, in which I did not think I derived much benefit.

In conclusion I would say that I do not think salicylate of soda or salicylic acid a specific for acute rheumatism; yet, if the treatment is begun at the proper time, and combine such other remedies as may be indicated, the most satisfactory results may be obtained.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——In a recent reprint Dr. G. W. H. Kemper, of Muncie, Indiana, describes the affections of the gall bladder which have a tendency to result in cutaneous biliary fistula. The particulars of eleven cases are reported.

——A surgical engine, armed with revolving knives, is described by Dr. H. Goodwillie, of New York City, in a reprint from the *Medical Record*. He has made use of it for the successful removal of adhesions of the soft palate against the pharynx, nearly closing up the naso-pharyngeal passage. It has been successfully used in trephining the antrum, mastoid cells, exposing the superior and inferior dental nerves, opening abscesses, resections of the jaws, removal of epulic growths. Indeed, in many other surgical operations on any part of the body, it can be most efficiently used.

BOOK NOTICES.

Analysis of the Urine, with Special Reference to the Diseases of the Genito-urinary Organs. By K. B. Hoffman and R. Ultzmann. Translated by T. Barton Brune, M.D., and H. Holbrook Curtis, PH.B. New York, D. Appleton & Co., 1879.

This is the same German work which we noticed as translated by Dr. Forscheimer, and published in Cincinnati a few weeks since. It is an unfortunate occurrence for both parties, and some measure should be adopted by translators to avoid this simultaneous work on the same book. It is fair to state that Dr. Brune says in

his Preface that his translation has been made with the assent and under the supervision of Dr. Ultzmann, one of the authors. It also contains several well executed plates, showing the sediments in the urine, which do not appear in the other translation. So far as the respective merits of the translations are concerned, we cannot say much, as the original is not at hand; but in the very first sentence of the introduction there is a palpable error in Dr. Brune's translation. We quote the two translations:—

By Dr. Brune.—"The results of the generally complicated chemical processes upon which depends the basis of animal life, are, on the one hand, the building up of the body, and on the other, the breaking down of the same, both included in the common term, 'retrograde tissue metamorphosis.'"

By Dr. Forscheimer.—"The results of those processes, usually complicated, which go to make up the basis of organic life, are, on the one hand, the building up of the body; on the other, changes which have been collectively termed 'retrograde metamorphosis.'"

Clearly, Dr. Forscheimer's translation is the correct one; and it is also more elegant, for to speak of a basis *depending* on something is an unfortunate selection of words.

Here is another comparison:—

Dr. Brune.—"By his successors in the Arabian school nothing of importance was added, although, particularly in the East, each court had an examiner of urine."

Dr. Forscheimer.—"Otherwise the Arabic physicians did nothing of importance, notwithstanding the presence of an uroscopist at every court throughout the Orient."

Obviously, the latter translation conveys more accurately the author's meaning.

We shall not pursue the comparisons; probably a fair statement would be that Dr. Forscheimer's is the better translation, while Dr. Brune's is the handsomer book.

Clinical Medicine; A Systematic Treatise on the Diagnosis and Treatment of Diseases. By Austin Flint, M.D., etc. Philada., H. C. Lea. 1 vol., 8vo, pp. 795.

The success which for many years has attended the teaching of Dr. Flint puts it beyond doubt that when he writes a book for the student and practitioner, it will be replete with well digested information, carefully presented, and of an instructive character. All this can be said of the work before us. In it he confines his attention to the presentation of the two great practical objects of medical science, diagnosis and treatment. He speaks on these subjects with the erudition of a scholar and the experience of a practicing physician of nearly half a century's observation. We cannot do better than to turn, almost at random, in the volume, and indicate its character by one or two sections.

A little over a page is given to cholera infantum. Under this term, the author says, is included cases of functional diarrhœa, colo-enteritis, and true choleraic affection. As to treatment, the safest is, as a rule, to arrest the affection at once with small and repeated doses of opium by the mouth. The dietetic regimen is also insisted upon.

About three pages are devoted to tapeworms. The author's experience gives the preference to the male fern as a tænicide.

Delirium tremens occupies three pages. The author believes that alcohol, opium, the bromides, digitalis and chloral, are all efficacious, but he does not define in which cases the one or the other is preferable. He thinks half an ounce of the infusion of digitalis will secure all the benefit to be derived from this drug, although as much of the tincture may be given with safety.

On the debated topic of croup and diphtheria the author takes the position that diphtheria is a general disease, an essential fever, which is complicated in a certain proportion of cases by pseudo-membranous laryngitis or croup. He doubts that any specific remedy for diphtheritic fever has yet been discovered, though he inclines to think Dr. Chapman's claims for alcohol are not irrational.

So, also, he introduces pneumonia as an essential fever, of which the pneumonitis is the anatomical characteristic. Antipyretic measures are recommended, but the cold bath is not heartily indorsed. Counter irritation is spoken of as "more than doubtful." The risk in bloodletting, he thinks, has been exaggerated of late years. Moderate stimulation is often serviceable.

These notices will show the scope and extent of the work. The diseases are classified into general and local, according to the usual nosology now in vogue, and there is an introduction of forty pages, on clinical records and reports, the physiognomy of disease, the pulse, thermometry in disease, simulation of disease, hygienic and expectant treatment, etc. The book will not fail to give satisfaction to the purchaser, and will add to the already wide reputation of the author.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Half-Yearly Compendium of Med. Science,	**2.50**
Reporter and Compendium, - - -	**7.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**8.25**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE CONSTITUTIONAL PROTECTION OF STATE MEDICINE.

A very thoughtful address, full of excellent suggestions, was made to the last meeting of the Louisiana State Medical Society, by Dr. STANFORD E. CHAILLÉ. The subject was "State Medicine and Medical Organization." We hail it as a refreshing indication of the growing appreciation of this, the most important of all the branches of medicine.

The published copy of this address also contains a series of provisions in the interest of State Medicine, recommended for adoption to the Louisiana Constitutional Convention, which assembles this year to frame a new constitution for that State. These provisions were unanimously approved by the State Medical Society, and most of them, if included *and enforced*, would prove of incalculable benefit to the State. Among these provisions are several which are in advance of the appreciation of the age, perhaps, but none which are ahead of its needs. Of the more striking, we may specify the recommendations that the Legislature shall provide for the interests of State Medicine in all its departments; for public hygiene or preventive medicine; for medical education; for institutions for the sick and infirm, and for medical jurisprudence; for the establishment and maintenance of a State Board of Health and Vital Statistics for the whole State, with parish or municipal boards subordinate thereto; for the protection of the people from all contagious and infectious diseases, and from all preventable causes of disease and death; for the protection of the people from unqualified practitioners of medicine, surgery, midwifery, pharmacy and dentistry; for the maintenance of the University of Louisiana, and its three departments of literature, medicine and law; for the protection of confidential communications made by patients to physicians; for preventing the advertisement and sale of all fœticidal drugs or instruments, and of all drugs detrimental to the interests of health and morality; for the adequate compensation of scientific experts in all cases; for the separate trial of criminals alleged to be insane on each issue—first that of insanity—and that adequate time and opportunity shall be given to medical experts to test the question of insanity. No persons shall be allowed to testify as expert witnesses to matters of scientific opinion, except those recognized as competent experts in such matters by their own profession, as organized under the laws of this State. Only qualified practitioners shall be expert witnesses in the courts to medical facts; the legal duties of coroners shall be assigned exclusively to experts in law, and their medical duties exclusively to experts in medicine.

How essential it is to have these provisions incorporated into the fundamental instrument of the existence of the commonwealth is ably shown by Dr. CHAILLÉ in his address. It appears, for example, that there is not a State which has laws encouraging, for sanitary purposes, either drainage or irrigation. Massachusetts, in 1849, effected a sanitary topographical survey, which proved of great value, and a second one was in 1875 instituted by New York; but other States have neglected this important matter; and instead of guiding the immigrants whom they seek

to entice with trustworthy health maps, they supply them with the seductive but false certificates of ignorant residents, who base their worthless convictions on such facts as that they are not dead yet, and that several of them, who, however, never happen to have about them a legal record of the date of their birth, are one hundred and more years old!

Some States have laws to protect property and life from explosive illuminating oils, but in most or all of these States the greed of gain has so emasculated these laws that property is still endangered, while health and life are sacrificed.

We heartily sympathize with the feeling which induces Dr. CHAILLÉ to express himself in the following strong terms:—

"After many years of special study, each additional year has increased my conviction that wherever social order has been firmly secured by law, there the supreme subject of importance is, *the avoidable causes of disease and death, their extent, cost and influence on morality and human progress.* This subject is so exhaustless, so varied in detail, so fruitful to study and discovery, and so little understood by the public, that I confess my impatience whenever a physician discourses to a public audience on any other subject."

NOTES AND COMMENTS.

Therapeutical Notes.

DIGITALIS IN HEART DISEASE.

In the weak heart of elderly persons Dr. Fothergill combines digitalis with chloroform—

℞.	Tinct. digitalis,	♏x	
	Sp. chloroformi,	♏xx	
	Infus. buchu,	℥j.	M.

For one dose.

In conditions of debility, where it has to be taken continuously for months or years at a time, he recommends it in pill form, combined with iron and bitters, as—

℞.	Pulv. digitalis,	℥j	
	Fer. sulph. exsic.,	ʒ ij	
	Strychniæ,	gr. ij	
	Pulv. pip. nig.,	℥ ij	
	Extr. gent.,	℥ ij	M.

For sixty pills. One or two twice daily, after meals.

GLYCERINE IN HEMORRHOIDS.

Dr. William Lee, of Baltimore, calls attention, in a recent report, to the beneficial results of glycerine in the treatment of the troublesome and painful complications accompanying internal hemorrhoids. He states that in six cases of the above named affection he has tried it with most satisfactory results.

The dose of glycerine for these troubles must be small and continued for some time; although its modus operandi is at present not well understood, the action it has upon the rectum seems to be of a specific nature.

ARTIFICIAL KOUMISS.

The following process is given by a correspondent of the *Pharm. Zeitung*:—

Condensed milk,	100 grams
Lactic acid,	1 "
Citric acid,	50 centigrams
Good rum or brandy,	15 grams.

Diluted with water to 1000 or 1500 grams, and charged with carbolic acid.

After standing in a warm room for a few days the mixture will commence to foam.

ACONITE IN PNEUMONIA.

Dr. A. C. F. Rabagliati writes, in the *Practitioner*, August, 1879: It has been my practice, for years, to treat incipient pneumonias, and also other simple inflammations, by aconite, which, however, I have found it convenient to use of one-tenth of the strength of the pharmacopœial tincture, the remaining nine-tenths being rectified spirit. Aconite acts in simple inflammations by combating the reaction of cold, which is commonly, but only by oversight, called inflammation.

The Therapeutical Powers of Fuchsine.

A few years ago the large employment of fuchsine to color wines raised a great noise in France. The chemists said it was a poison, and there was much talk of its evil effects. In a recent memoir, however, on the subject, MM. Bergeron and Clonet conclude that the admixture of fuchsine is perfectly harmless, and even remark that in one case of cardiac albuminuria, where the falsified wine had been employed, the albumen had completely disappeared during its administration. Further experiments by Feltz and Duclos show that fuchsine can be taken in daily doses of eight grams, and that it, therefore, is not a poison. When symptoms of irritation (diarrhœa) do occur, they are due to the small quantities of arsenic which it often contains. Therapeutically, fuchsine is a diuretic, and causes an increased elimination of phosphates. A thesis of M. Divet on "Fuchsine in the Treatment of

Chronic Albuminuria and of Parenchymatous Nephritis" contains an account of sixteen cases, in which marked and rapid benefit was obtained during the administration of this substance. M. Dieulafoy has given an analysis of this thesis, and of four cases treated by him at Menilmontant. Fuschine was given to these patients in doses of fifteen centigrams daily, sometimes alone, sometimes in conjunction with other remedies. The general action was found to be *nil;* no improvement being obtained either in the thoracic, cephalic, or cardiac symptoms (dyspnœa, headache, vertigo, palpitations). Locally, the action of fuschine was uncertain and irregular; it was not diuretic, but sometimes appeared to moderate the desire for frequent micturition.

The Relation of Memory.

The *Medical Press and Circular* gives some entertaining statistics of memory, from M. Delaunay. The inferior races of mankind, such as negroes, the Chinese, etc., have more memory than those of a higher type of civilization. Primitive races which were unacquainted with the art of writing had a wonderful memory, and were for ages in the habit of handing down from one generation to another hymns as voluminous as the Bible. Prompters and professors of declamation know that women have more memory than men. French women will learn a foreign language quicker than their husbands. Youths have more memory than adults. It is well developed in children, attains its maximum about the fourteenth or fifteenth year, and then decreases. Feeble individuals of a lymphatic temperament have more memory than the strong. Students who obtain the prize for memory and recitation chiefly belong to the former class. Parisian students have also less memory than those who come from the provinces. At the *Ecole Normale* and other schools the pupils who have the best memory are not the most intelligent. The memory is more developed among the peasantry than among citizens, and among the clergy than among the laity. The memory remains intact in diseases of the left side of the brain, and is much affected in those of the right, from which it may be inferred that the right side is more the seat of this faculty than the left.

From a physiological point of view memory is diminished by over feeding, by physical exercise, and by education, in this sense, that the illiterate have potentially more memory than those who know how to read and write. We remember, moreover, better in the morning than in the evening, in the summer than in the winter, and better in warm than in cold climates.

Emotional Legislation.

A few years ago a female correspondent wrote to the *Nation* that the "beats" who lead astray the ignorant girls who come to New York city should be hanged; and that cynical paper quoted the letter as illustrating how unqualified the female mind is, as yet, for law making. But there is a stronger example before us. Out in San Francisco is published a "Medico-literary Journal," edited by an M.D. of the female persuasion. In a recent number she mentioned a marriage in that city, in which the bride was thirteen years old, and referred to the clergymen who solemnize such marriages in the following manner:—

"If we could, we would, together with the M.D.'s who have said along the past ages that women mature sooner than men, burn them at the stake, as a man burns his last year's stubble, that he may have a clean field for a new crop. We should quiet our nerves by remembering how calmly these human vampires have aided the sure sacrifice of throngs of unsuspecting young girls, of twelve and fifteen years of age. . . . Yes, we would gladly light the torch that would send the lurid flames to high Heaven, and by the broad glare write in the hearts of an aroused people, Marriage and Motherhood shall be *respected.*"

San Francisco is a great place for law making, with its Kearneys and Kallochs and this one.

Statistics of Delirium Tremens.

Dr. Näcke, of Dresden, has published the result of an extensive study of delirium tremens as it occurs in that city. It is rare from the use of wine or beer, and most frequent of all from potato spirits (amyl alcohol). The most common age is thirty-five to forty years. The highest temperature observed was 38.8 C. When the mercury exceeds that, some complication, usually pneumonitis, is present. Albuminuria was found in eighty-two per cent.! This usually disappeared with the disease. The illusions are nearly always those of depression and persecution. About one-third have visions of animals, not only snakes and rats, but large animals, as dogs, lions, etc. The mortality he puts as high as twenty-four per cent., which is a far worse showing than in this country. He also says that the first attack is much the most dangerous, which is contrary to the prevailing opinion. His treatment is full doses of chloral.

The Solar Cautery.

It is curious to observe how many old projects are furbished up and brought out as new, or are re-discovered. In a late number of an Italian journal, the *Gazeta Medico-Italiana*, an Italian physician has much to say of the successful use of the heat of the sun, condensed by a lens, for the destruction of nævi, etc. This supposed discovery has been quoted in the French, English and German journals as something new. More than fifteen years ago it was thoroughly aired in the Medical and Surgical Reporter, and the experience then obtained shows that the suggestion is of no practical value.

Therapeutic Value of the Melia Azedarach.

The handsome tree, so common in Carolina and Georgia, known as the Pride of India or Pride of China, botanically the *Melia Azedarach*, has considerable reputation as an anthelmintic. An examination of it by Mr. J. Jacobs, published in the September number of the *American Journal of Pharmacy*, shows that its active principle is a yellowish-white resin found in the liber of the bark. He thinks a fluid extract or tincture of it would be a valuable addition to the Pharmacopœia. About three grains of the resin may be given to a child of three or four years. The taste is strongly bitter, and in that respect it is at a disadvantage.

Correspondence.

The Causes of Cholera Infantum.

Ed. Med. and Surg. Reporter:—

I read with much interest an article in the Reporter, of August 30th, by Dr. Frank Woodbury, on cholera infantum. The Doctor gives more attention than it deserves, perhaps, to a paper of mine which appeared in the April number of the *Journal of Obstetrics*. This is probably due to the fact that I state my position more positively than more eminent writers who hold the same or similar views. The main object I had in view was to establish the proposition that continued high temperature is, in our climate, the prime or essential cause of cholera infantum.

The careful reader of my paper in the *Journal of Obstetrics* will understand that, as I am dealing with weekly and monthly mortality returns, my means of temperature are weekly and monthly means. A mean "above 75°," though not a very high mean for a single day, is well up for a month or even a week; for instance, a weekly "mean above 75°," is high in Philadelphia, and the week having that mean temperature would be called hot—hot for *weather*. I suggested a pathological kinship between cholera infantum and sunstroke or heat stroke, on the following grounds:—

1st. The same conditions seem to be sufficient for and essential to the development of each. 2d. They come and go together. 3d. The development is gradual and the recovery is slow in each, showing a profound impression made on the living power of the patient. 4th. The explosive character of the attack under the cumulative effects of continued high temperature, with the sudden severe or fatal prostration consequent. A condition of malnutrition or malassimilation is established before the explosion, and persists stubbornly afterward. It would seem that the blood, under the influence of the continued high temperature, is degraded, impaired in some of its vital qualities. A cachectic condition is established, which continually becomes more profound under the persistent operation of the causes which brought it about.

The lines which represent the mortality from each rising and falling together and along with the rise and fall of the thermometer, suggest related causes, and why not related effects? I allow the suggestion to stand for proof or disproof, either of which will be equally gratifying to me; light is more to be desired than championship.

When I quote from the circular of the New York Board of Health, "Wash your well children in cold water twice a day, and oftener in the hot season," I understand cold water to mean hydrant water; this is not cold water for drinking purposes when the thermometer is in the "nineties," but the people to whom it was more especially addressed would probably use hydrant water (not ice water) in carrying out this direction, with very desirable effect on the mortality returns, as regards cholera infantum, as I have good reason to believe and don't hesitate to repeat; let it be proved that this is a mistake; let it be put to the test.

It may be totally impossible to distinguish between cholera infantum and cholera Asiatica when they both prevail, yet few would question but that they are pathologically different, and fewer still would count them etiologically identical. If we may ignore the difference therapeutically, it does not follow at all that prophylactic measures should be the same with reference to each.

Although the thermometer does not reveal a difference between solar and artificial heat, animal and vegetable physiology pronounce them different. The comparison between furnaces, superheated nurseries and animal heat on the one hand, and the weather of midsummer on the other, is amusing, and yet amazing. It may be quite preposterous, from a theoretico-physiological point of view, to assume that a temperature ranging daily between 70° and 95°, continued for a week or more, is sufficient to cause cholera infantum, or any other disease, for that matter, but it is a *fact* that under such conditions, as to temperature, certain diseases *do* appear, and in the absence of this continued high temperature they *do not* appear; and facts must be faced, whether at first sight they look reasonable or not.

Dr. Woodbury says, "Another reason why heat is not the sole cause is given by Eberle. and

is abundantly confirmed by others—that the disease is much more prevalent in our large cities than in the country, where the temperature is equally high, and may be even higher." Further on he says, "Cholera infantum occurs most frequently in cities, *because* its victims are there crowded in greatest numbers. It is not, however, confined to the cities, but encountered, *in all its severity*, in suburban and country residences; this more elaborate statement seems to be brought out by the exigencies of the "ground-water" theory, for the ground waters "do move" in the country as well as in the city.

Now solar heat is a most formidable antagonist for the physician to contend with, it being almost impossible to influence the weather to any great extent; but who can hope to counteract the malign influence of "the movements of the ground water?"

These movements may cause the giving off of impalpable and mysterious effluvia, and they may put the ground in a condition favorable to the taking away of some mysterious health conserving influence from the air. The subject of the influence of "telluric exhalations" and inhalations is hopelessly abstruse, and I would hesitate to say that these influences might not have a hand in the causing or hindering of almost anything under the sun.

The summing up of "the prophylaxis and treatment of cholera infantum," in the simple recommendation to "send the little sufferer to the seashore," is a prescription simple enough for the physician, but utterly impracticable in nineteen out of twenty cases, even in Philadelphia, to say nothing of cities, towns and communities hundreds of miles inland; and besides all this, it is not altogether certain that the "ground water always moveth itself aright," even at the seashore; New York and Brooklyn lose largely by cholera infantum, yet they cannot properly be called inland cities.

I think I can see that the height or "movements of the ground water" might be affected by ten days of continued high temperature, but I cannot conceive that a fall of temperature of a few degrees for a day or two at the end of that time could be expected to cause these waters to be "troubled" in a more healing way; yet there is no doubt but that this fall of temperature would be attended by an improvement in those already sick from cholera infantum, and an immediate falling off in the number of new cases, and also, of course, a falling off in the number of deaths.

T. Clarke Miller, M.D.

Massillon, O., Sept. 10th.

The Bag of Waters as a Dilator in Labor.

Ed. Med. and Surg. Reporter:—

On the 22d of Aug. 1879, I was called in to see Mrs. G. S., in labor; age 19 years, primipara, enceinte 9 months (her full term). Dr. F. had charge of the case, but owing to indisposition was unable to attend further. The Doctor told me that some two weeks previous she had sustained an injury on jumping from an open wagon; after this she was slightly indisposed, and suffered from pains of a uterine character, although kept up and continued quite well, except that she felt no movements of the child in utero from the time of the accident. The Doctor was satisfied that there was no vitality existing in the fœtus, but declined to use any means to bring on delivery, rather trusting to nature, only giving a tonic, consisting of quinine and iron. This prescription she had taken for several days, the Doctor also stating that she was from a malarious district, and that labor had been slow and tedious, and that the presentation was, in his opinion, that of a foot or arm. This opinion, of course, was supported by the projection of the bag of waters conically. So much for the Doctor's history of the case. On touching I found, as the Doctor stated, a considerable conical projection; could not detect, by touch, anything resisting; therefore was forced to the conclusion that we would wait further dilatation, then turn and deliver. This course was agreed to, and the Doctor took his leave. I now perceived that the patient was growing impatient and restless, as well as the nurses (who were three in number); doubtless this was occasioned in part by the change in physicians, as well as non-interference with the case. I must confess that much anxiety on my part awaited the result of the case; in fact, I was looking for trouble ahead, but kept apparently brave, cheered my patient and inspired confidence in the nurses by telling them that all was right so far, that labor had to advance more yet before I could assist her any; I continued doing nothing.

After waiting, however, fully three hours, I took my seat by the bedside, intending to rupture the membranes, thrust in my hand and turn; just as I was ready to act the waters broke. On touching I felt something, but did not know what it was; making traction gently, it came forward, without shape, and a pulpy mass. I was at a loss to know what I held in my hands; on turning aside the cover I found, to my astonishment, that it was the head, the bones of the face and skull being completely broken down and leaving a large saccular mass measuring some fifteen inches flatwise. Now I reached up, pulled down the arm and delivered, the body being a putrid mass also; there was not a particle of hemorrhage; the placenta being adherent I introduced my hand into the uterus, peeled it off and turned out the clots; now I washed out the organ with a strong solution of carbolized water, tepid, and ordered my patient's linen changed and had her removed to a comfortable bed. She now appeared almost exhausted, exhibiting symptoms of blood poisoning, as "coming events cast their shadows before." I began to fortify the system against that much dreaded affection, *septicæmic poison.* I used alcoholic stimulants freely, quinine extravagantly, and alimentation abundantly; these, with the local injections of carbolized washes, continued for several days, doubtless saved my patient from an untimely grave. After a few days elapsed I had the pleasure of meeting the Doctor; he remarked, as he approached me, "you had to turn and deliver." I answered "no." This seemed to puzzle the Doctor; I explained that it was a head presentation, the conical projection being nothing more than a preternatural *caput succedaneum.* And further, in conversation with the Doctor, he expressed himself as

believing that advanced fœtation bore an immunity over a more recent impregnation; this he says has been his experience. If the Doctor is correct in this, what is it due to? is it owing to the membranes, being more mature and remaining intact, holding the waters, thereby preventing the absorption of the debris? And now, reverting to my caption, I hold that the best dilator is the bag of waters, more especially in a primipara; it is always slow, steady and efficient; it proved itself a *sine qua non* in this case, as well as others that I can attest to in its favor.

If the membranes had been ruptured early in this case it would have doubtless necessitated embryotomy; its delay made it an easy and practical delivery. E. W. Rush, M.D.

Paris, Texas, Sept. 10th, 1879.

The Doctor his Own Druggist.

Ed. Med. and Surg. Reporter:—

I am glad to see in your valuable journal the recent discussion on the "crookedness" of physicians and druggists, but I must confess I see but little difference in the grounds taken by yourself and Dr. Lyon.

No one, I presume, denies to the country physician the right to dispense and charge for the medicines necessary in his practice. You would hardly find a physician who would defend the practice of doctors who compound with druggists to defraud the patient by exacting a percentage on prescriptions.

The question, then, in the discussion seems to be: Is it professional, is it right, for a physician who is convenient to retail drug stores to "keep on hand," dispense and charge for the medicines necessary in his own practice? If he has the right to dispense them, he undoubtedly ought to be allowed to charge, at least, cost for them. To furnish medicine gratis would be a tax most doctors could not long "hold out" at.

I do not know that the practice of dispensing and charging for medicines by the physician has ever been condemned by the American Medical Association or any "regular" State or local medical society.

Unless he has had the advantages of a course in pharmacy, or better opportunities in the medical college laboratory than most students have, there is no plan which offers better means to the young physician of familiarizing himself with the dose, physical properties, and chemical action and reaction of medicines, than the dispensing of his own drugs.

When one does an extensive practice, especially an office practice, it is often difficult to recollect the remedies prescribed, unless a note is kept of each case. In dispensing his medicines, the sense of sight, and often of smell and taste, is brought to the aid of memory in calling to mind the treatment instituted. It is a sad comment upon the honesty of our drug men, but, nevertheless true, that there are druggists who will substitute cheaper for more expensive drugs—as sulphate of cinchonidia for sulphate of quinia—give light weight, and, in many instances, leave out ingredients altogether. This, with the many unintentional mistakes—their prescribing for the sick; the repeating of prescriptions without authority; the putting up and selling of proprietary medicines; and many other tricks of the trade—releases the doctor from any obligations he might otherwise be under to patronize the druggist, and make it not only justifiable for the physician to dispense his own medicines, but in many instances to the interest of the patient himself, and the reputation of the profession at large. S. W. Johnson, M.D.

Ennis, Texas.

Sulphate of Morphia, Hypodermically Injected, in Asthma.

Ed. Med. and Surg. Reporter:—

Not having seen any reference in medical literature to the use of sulphate of morphia hypodermically in asthma, is my apology for asking a brief space in your valuable journal, by which I may bring the matter before the profession, and through them confer a great blessing upon suffering humanity. During the past twelve months I have treated several bad cases most successfully by the above named method, using it in ¼ to ½ grain doses once in twenty-four hours, usually in the evening; and through the day using some expectorant, such as iodide of potassium, lobelia, acetate morph., wild cherry, etc., combined or separately, as the case might seem to demand, varying the amount of each to meet the characteristic symptoms as they existed. And in each case so treated I have been well pleased with the result—speedy relief in five to ten minutes—a blessing to the sufferer.

Wilmington, Del. S. Leslie West, M.D.

News and Miscellany.

National Pharmaceutical Association.

This Association convened at Indianapolis on the second week in this month. A number of valuable papers were read. On one day the Convention indulged in a lively discussion over the admission of patent medicine men, brought on by voting one from New York into membership. After considerable attention was paid to the matter, it was finally decided to expunge from all minutes all debates, and permit him to remain as quietly as possible.

Saratoga was chosen as the place of holding the next meeting.

Filth Diseases.

Of scarlatina, diphtheria and typhoid fever, Dr. Snow writes, in his last report as health officer of Providence: These three diseases are undoubtedly caused, to a very great extent at least, by impure air, and in some cases, by impure water. Those who are breathing habitually, and especially in the night time, the impure air from privy vaults and cesspools *are in special danger*. Let every housekeeper insist upon a thorough cleansing and disinfection of these deposits of filth, and many lives will be saved in Providence during the next eight months.

The Discovery of Anæsthesia.

The war as to the priority of the discovery of surgical anæsthesia threatens to break out again, owing to the advocacy of Dr. Long's claims by Dr. Marion Sims. The defenders of Morton, Jackson and Wells are promptly rushing to the rescue of their favorite champion. The Boston *Medical and Surgical Journal* has entered the field with its well known rallying cry; and the dental surgeons are not slow to take up the cudgels for Dr. Wells. We have an article kindly sent us, showing the claims of the latter, by Dr. E. H. Bowne, of Fredonia; but we really think the conflict was so thoroughly fought out at the last bout that it is not worth while stirring the dust so soon again.

No sooner has Dr. Crawford W. Long's claims been solidly laid and well witnessed, than another claimant turns up, who brought it to the attention of Dr. Long. This was a student in his office, still living in South Carolina, by name Wilhite. A letter from Atlanta announces that his friends intend to push his claim, so that soon, perhaps, we shall hear more of him.

Surgery Among the Zulus.

The Zulus, like the "Peculiar People," have no respect for the arts of surgery and the drugs of doctors. A British surgeon writes of them—

"The few wounded Zulus under our care absolutely refuse any operation or treatment; they even take off splints as soon as applied. But, in spite of their stupidity, they do very well, and one has the opportunity of observing the natural history of gunshot wounds and fractures. They somehow crawl out of doors every day, and nurse their fractured limbs with both hands, squeezing the wounds a good deal, and constantly washing them with a small stream of water, which they very cleverly manage to eject from their own mouths on to the wounds, though held at a distance of two feet or more. One man, shot through the head of the tibia—a fearful smash, knee joint opened in all directions—has got *quite fat* under the above treatment and ordinary soldier's rations; the joint is, of course, in very bad position, but I suppose he will eventually recover, like a dog or cat which has been trapped or suffered other injury."

German Physicians as Practitioners.

The unfavorable opinion we have heretofore expressed of the therapeutics now generally to be learned in Germany has been endorsed by several physicians who have recently returned from there, and is supported by the observation of Dr. Willard Parker, of New York. This eminent and venerable teacher recently remarked: "The Germans are preëminently theorists. The result is that when a German physician or surgeon comes to treat a particular case he is apt to follow the teachings of his master to the letter. This will not do, for there can hardly be found two cases which require precisely the same treatment. For this reason the American, who is naturally ingenious, when he comes to a case, will set to thinking on his own hook, and will devise some way to get successfully through with it."

A New Hospital.

At a stated meeting of the Schuylkill County Medical Society, the following Preamble and Resolution was offered by Dr. D. W. Bland:—

WHEREAS, The prospect for the erection of a General Miners' Hospital in the Anthracite region is now about to be fulfilled, the Schuylkill County Medical Society, feeling a common interest in the success of said Hospital, therefore,

Resolved, That Dr. G. W. Brown, Dr. D. J. McKibbin and Dr. J. T. Carpenter, are hereby appointed as a representative committee from the Schuylkill County Medical Society, whose services are offered to the commission of said Hospital, to aid and assist in the perfecting of such plans in building as will combine all the modern improvements in the construction of General Hospitals.

Manufacture of Chemicals in the United States.

Half a dozen years ago we imported from France annually six million pounds of cream of tartar; now we do not bring over a pound, and the price is one-third less than it was then. At that time we sent to France and England yearly for half a million pounds of tartaric acid; last year we imported only 183 lbs.! Citric acid was then sold to us at the rate of a quarter of a million pounds yearly, at a price of $1.30 per lb.; last year only 27,000 pounds were brought in, and the price was 57 cts. per lb. A million pounds a year of borax was then sent us, at 35 cts. per lb.; last year only 3500 lbs., at eight cts. per lb.; while we sent to other countries two million pounds! Are not these wonderful statistics for "hard times?"

Health of the Navy.

The following statistical returns, made to the Navy Department, exhibit the aggregate sick report of the several squadrons for the second quarter of 1879:—

United States South Atlantic Squadron.—Total number of men, 564; total sick days, 1131; daily average number of sick, $12\frac{39}{91}$; total cases treated, 120.

United States European Squadron. Total number of men, 1161; total sick days, 5121; daily average number of sick, $56\frac{28}{91}$; total cases treated, 580; deaths 2—1 enteric fever, 1 suicide.

United States Asiatic Squadron.—Total number of men, 1091; total sick days, 2704; total cases treated, 357; daily average number of sick, $29\frac{69}{91}$; deaths 2, from drowning.

Unprofessional Testimony.

On a suit for divorce, in Cincinnati, recently, a physician testified that the defendant came to his office about two years ago suffering from a private disease, and that he prescribed for him. Recently the witness was called on by a detective, who made inquiry as to the fact of his having given such a prescription to a man so named, and the witness went with the detective and identified the man. This physician seems to have been a regular graduate, and at one time, if

not now, connected with one of the colleges. That such action is an unpardonable violation of professional honor should be universally recognized.

The Question of Bills.

The physicians of the city of Quincy and county of Adams, Illinois, have taken a decided step toward putting the profession there on a proper financial basis. They have adopted a series of resolutions, of which the following are the gist:—

Resolved, That we, as physicians and surgeons of Adams county, when called upon to treat a patient, consider our bills due as soon as services are rendered.

Resolved, That we render our bills on the first of every month. That in the county, outside of the city of Quincy, the time for rendering bills be such as may be agreed upon by the practitioners of the different localities.

Resolved, That we, as physicians and surgeons of the city of Quincy, employ a common collector to collect our bills, and that the physicians of the county be recommended to employ a collector for one or more townships, and that each collector keep a delinquent list for the benefit of the physicians of the city and county.

Some such action as this should be generally adopted for the protection of the profession and for the inculcation of honesty toward doctors in the public.

The Yellow Fever

Has still indicated extreme virulence in Memphis. For instance, on the 16th 29 new cases and 9 deaths were reported. Several of the neighboring towns have become infected; but the latest reports point to diminishing numbers.

On the 18th quarantine in Cincinnati was raised, which was sixty days from the time of its establishment. There has not been a case of yellow fever there since July. Before that time there had been six imported cases, one of which was fatal.

On September 16th, the Board of Health of Louisville raised the river quarantine against Memphis. Seven cases of yellow fever were treated there this season, all imported. Four of the number died.

Personal.

Dr. Ackland, F. R. S., Professor of Medicine in the University of Oxford, President of the Council of Medical Education for Great Britain, and honorary physician to the Prince of Wales, whom he accompanied to this country in 1860, is in this city, the guest of Professor Gross.

Items.

Corrections.—On page 217, current volume, the amount of strychnia should read .02.

The graduation fee of the Jefferson Medical College is $30.00, not $20.00, as stated.

In our notice of the Mackinnon Pen we did its capacity an injustice. It will write nearly thirty pages of manuscript.

Smallpox.

In Northeastern Mexico smallpox is reported as epidemic.

In Roma, Texas, ten children have died. The ranches in the vicinity are badly infected.

OBITUARY NOTICES.

—Dr. Robt. W. Scott died, August 24th, in Milan, Tenn., at his home, of traumatic abscess of the pleura, caused by a fall from his horse. He was an esteemed practitioner.

—Last week we announced the death of Ex-Surgeon General Finley. He was born at Newville, Cumberland county, Pa., in 1797. He studied medicine at Chillicothe, Ohio, where he graduated in 1818. He immediately entered the United States Army, as Surgeon's mate of the 1st Regiment of Infantry, and subsequently filled the position of assistant Surgeon, and was medical director in the field in the Black Hawk, Seminole and Mexican Wars. He passed eight years on the frontier in Arkansas, Louisiana and Florida, and was on one of the earliest expeditions to the Rocky mountains, in 1834. In 1861 he succeeded General Lawson as Surgeon General of the United States Army, and in 1862 was retired from active service on his own application, after having served forty-four years.

QUERIES AND REPLIES.

Dr. T. C., of Pa.—Dr. Churchill's syrup of the hypophosphites, comp., is of different strengths. His authentic formulæ will be found in Napheys' *Medical Therapeutics*, Sixth edition, p. 195.

Dr. A. J. K., of Pa.—1. Tenotomy in talipes varus should be resorted to, according to Ashhurst, between the second and third months of life. 2. With the proper precautions, artificial anæsthesia is safe at that age.

Dr. A. E. C., of Iowa.—The profession very generally, in this part of the country, favor the use of turpentine in typhoid fever, under the circumstances where it was particularly recommended by the late Dr. G. B. Wood (see *U. S. Dispensatory*, 13th ed., p. 618).

Ethics writes: "If Dr. A. has a case of injury requiring amputation; not having the necessary instruments, he calls on Dr. B. to bring his instruments and assist. Is it courteous in Dr. A. to use Dr. B.'s instruments, perform the operation, lift the arteries, etc., without first asking Dr. B. to operate or take any part, except to give the anæsthetic, and perhaps tie a ligature?"

Ans.—The statement is incomplete. If Dr. A. asked the loan of the instruments and the aid of Dr. B., there is no criticism to be made; if he simply invited him to come with his instruments, and possessed himself of them without a "by your leave," he was not polite. It must be remembered that it was Dr. A.'s case.

Dr. L. B. T., of O.—There is no recent monograph on Massage in English. Dr. C. F. Taylor's "Movement cure" touches upon it.

MARRIAGE.

THACKER—RENO.—On August 26th, by the Rev. Dr. P. Tinsley, Rector of the Church of the Advent, at the residence of the bride's brother, Capt. John C. Reno, of Walnut Hills, Dr. J. A. Thacker, editor of the Cincinnati *Medical News*, and Miss Rebecca C. Reno.

Our brother editor has our felicitation in the happy event.

DOCTOR RABUTEAU'S

(Laureate of the Institute of France.)

DRAGEES, ELIXIR & SYRUP

Of Proto-Chloride of Iron.

"The experiments made in the hospitals of Paris have demonstrated that *Dr. Rabuteau's Dragees, Elixir and Syrup* regenerate the red globules of the blood with a rapidity never observed with the use of the other ferruginous preparations. These results have been proved by the various *Compt-Globules*.

"The ferruginous preparations of *Dr. Rabuteau* do not cause any constipation, and are perfectly tolerated by the weakest persons."—*Gazette des Hospitaux.*

Dr. Rabuteau's Elixir is prescribed when some difficulty is experienced in swallowing the Dragees; it is especially adapted to weak persons, whose digestive functions need strengthening or stimulating.

Dr. Rabuteau's Syrup is especially prepared for children, who take it readily, because of its agreeable taste.

MEYNET'S

DRAGEES OF COD-LIVER EXTRACT.

Careful experiments have established the fact that the **EXTRACT OF COD LIVERS** contains very valuable properties, which render it superior to the ordinary cod-liver oil. It is composed principally of *Gaduine*, large proportions of *Iodides, Chlorides, Bromides, Phosphoric Acid, Lime, Soda* and *Ammonia*, and especially *Propylamin*, all of which enter, but in very small proportions, into cod-liver oil.

These dragees of pure cod-liver extract take the place of cod-liver oil, and have been used with eminent success by medical celebrities of Europe in cases of *Scrofula, Rheumatic Affections, Rachitism, Phthisis*, and in all cases where a propylamic medication is indicated.

MEYNET'S DRAGEES are sold in bottles containing 100 dragees. Dose, 2 to 6 a day. Each dragee is equivalent to two tablespoonfuls of cod-liver oil.

MEYNET'S GRAINS are small granules intended for children. 10 are equivalent to 1 dragee.

E. FOUGERA & CO., New York, Agents for the U. S.

RIGOLLOT'S MUSTARD PAPER.

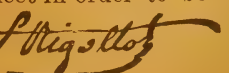
Is one of the most important and useful discoveries of the age, but it is not (as certain dealers of bad faith pretend) a preparation that any one can make, for it is not manufactured with a mustard that every one can buy.

RIGOLLOT'S MUSTARD PAPER.

Is the invention of Mr. P. RIGOLLOT, who is the exclusive owner; it is the only preparation which has been adopted by the civil and military hospitals and the armies and navies of France and England, and which has obtained a medal at the Centennial Exposition at Philadelphia. All other mustard plasters or leaves of whatever name, are but imitations of the original

RIGOLLOT'S MUSTARD PAPER.

Physicians will find it the most reliable sinapism, prompt and certain in its action, and will therefore always prescribe it. Every sheet in order to be genuine must bear the annexed signature of the inventor,



Sold in tin boxes containing 10 sheets, also 25 and 100 sheets, by all respectable chemists throughout the world.

E. FOUCERA & CO., Agents,

NEW YORK.

NEW REMEDIES.

FLUID EXTRACTS.

Coto Bark.—From BOLIVIA. Almost a specific in acute and chronic diarrhœa, cholera, cholera morbus, etc.

Cascara Sagrada.—(**Rhamnus Purshiana.**) From the PACIFIC SLOPE. A certain remedy for habitual constipation; and very useful in all cases where a laxative or cathartic is indicated. Beware of the fluid extracts of spurious varieties of this bark.

Folia Carobæ.—From BRAZIL. A powerful alterative, which exerts a marked curative action in syphilis, scrofula and kindred disorders.

Rhus Aromatica.—A remedy in diabetes, and other diseases of the genito-urinary organs.

Damiana.—(**Turnera Aphrodisiaca.**) From MEXICO. The best known aphrodisiac. Of great value in impotence, spermatorrhœa, and loss of sexual appetite.

Boldo.—(**Peumus Boldo.**) From CHILI. The new tonic. Very useful in dyspepsia, hepatic torpor, yellow fever, etc.

Berberis Aquifolium.—From CALIFORNIA. Has marked alterative and tonic powers, and has been used with extraordinary success in salt rheum, psoriasis, eczema, scrofula and syphilis.

Black Haw.—(**Viburnum Prunifolium.**) From the UNITED STATES. Employed to prevent abortion and miscarriage.

Grindelia Robusta.—From CALIFORNIA. A valuable curative agent in asthma and diseases of the air passages.

Grindelia Squarrosa.—From CALIFORNIA. Anti-malarial. Used in enlarged spleen and other malarial diseases.

Cereus Bonplandii.—(**Cereus Grandiflorus and Cereus McDonaldii.**) From MEXICO. Heart sedatives. Very useful in controlling functional and organic disturbances of the heart.

Kaki.—(**Diospyros Kaki.**) From JAPAN. Peculiar action on the mucous surfaces. Useful in mucous dyspepsia, typhoid fever, etc.

Cercis Canadensis.—Indigenous. A positive remedy in chronic diarrhœa, dysentery, etc.

Jaborandi (diaphoretic). **Guarana** (sick headache). **Fucus Vesiculosus** (anti-fat).
Bearsfoot (enlarged spleen). **Coca** (nervous stimulant). **Kava Kava** (Gonorrhœa).
Eucalyptus Globulus (antiseptic and anti-malarial). **Yerba Santa** (coughs).
Yerba Reuma (catarrh). **Wood Betony** (dyspepsia). **Ustilago Maidis** (oxytocic).
Penthorum Sedoides (catarrh). **Soap Tree Bark** (tooth wash).

CRUDE DRUGS.

Goa Powder (ringworm and diseases of the skin). **Gurjun Balsam** (a substitute for Copaiba).
Alstonia Constricta (a substitute for Calisaya).

SUGAR-COATED GRANULES.

Calcium Sulphide 1-10 gr. (for the cure of boils and carbuncles).

Our limited space prevents our describing in detail the history and application of each remedy, but to those interested in NEW REMEDIES, we will say, that we can furnish interesting information relative to the above new drugs.

PARKE, DAVIS & CO.,

DETROIT, - MICHIGAN.

Our New Remedies can be procured of the Drug Trade throughout the United States. By specifying **"P., D. & Co.'s"** in all cases, you will ensure reliable preparations of the **true drugs.**

COMPRESSED
Coated Tablets.

I ask the attention of physicians to the above new and elegant form of preparing medicines.

The discovery and successful application of the process of compression to the coating of medicines with a thin envelope of chocolate, sugar, etc., thereby avoiding the application of heat and the employment of tenacious pill-mass excipients, marks a great advance in elegant pharmacy, and fully meets the requirements of a refined taste.

The process is available for nearly every medicine, including, besides those articles adapted to pill and powder form, several others, such as Chloral Hydrate, Iodide and Bromide of Potassium and Pepsin; while for Quinine and other bitter and nauseous remedies it is unsurpassed.

Owing to their small bulk, thinness and lenticular shape, they may be easily swallowed, and are readily taken even by children.

All officinal and standard unofficinal formulæ for pills, etc., are put up in this new form.

The prices will correspond as near as possible to the best made pills and granules in the market.

Chocolate coating is used regularly, unless the sugar is ordered.

Send for samples.

WYETH'S
DIALYSED IRON.

(FERRUM DIALYSATUM.)

A Pure Neutral Solution of Peroxide of Iron in the Colloid Form. The Result of Endosmosis and Diffusion with Distilled Water.

PREPARED SOLELY BY

JOHN WYETH & BRO.,

PHILADELPHIA.

This article possesses great advantages over every other ferruginous preparation heretofore introduced, as it is a solution of iron in as nearly as possible the form in which it exists in the blood. It is a preparation of invariable strength and purity, obtained by a process of dialysation, the iron being separated from its combinations by endosmosis, according to the law of diffusion of liquids. It has no styptic taste, does not blacken the teeth, disturb the stomach, or constipate the bowels.

It affords, therefore, the *very best* mode of administering

IRON

in cases where the use of this remedy is indicated.

The advantages claimed for this form of Iron are due to the absence of free acid, which is dependent upon the perfect dialysation of the solution. The samples of German, French and American Liquor Ferri Oxidi Dialys. which we have examined give acid reaction to test paper. If the dialysation is continued sufficiently long, it should be tasteless and neutral.

Our dialysed Iron is not a saline compound, and is easily distinguished from Salts of Iron, by not giving rise to a blood-red color on the addition of an Alkaline Sulpho-Cyanide, or a blue precipitate with Ferro-Cyanide of Potassium. It does not become cloudy when boiled. When agitated with one part of Alcohol and two parts of Ether (fortior), the Ether layer is not made yellow.

Physicians and Apothecaries will appreciate how important is the fact that, as an antidote for Poisoning by Arsenic, Dialysed Iron is quite as efficient as the Hydrated Sesquioxide (hitherto the best remedy known in such cases), and has the great advantage of being always ready for immediate use. It will now doubtless be found in every drug store, to supply such an emergency.

Full directions accompany each bottle.

Physicians will find our DIALYSED IRON in all the leading drug stores in the United States and Canada.

It is put up in bottles retailing for **ONE DOLLAR**, containing sufficient for four months' treatment Large size is intended for hospitals and dispensing. Retail at $1.50. Price Lists, etc., sent on application.

CASES OF IMPACTED CÆCUM AND COLON.

BY E. R. MAXSON, M.D., L.L.D.,
Of Syracuse, N. Y.

As most of the cases of this character, of long standing, to which I have been called, had been regarded and treated as other affections, I offer the following, which have fallen under my treatment during the past two years, hoping to throw some light upon the subject:—

June 28th, 1878, I was called to attend a boy, about nine years old, of good parentage, who was suffering from tuberculous meningitis, as was evident from all the symptoms of that disease being fully developed, but which I need not enumerate.

On inquiring into the cause, I found that from infancy he had been badly constipated; and for years had lumps in his bowels, which had been regarded as "tumors" of some kind, not defined.

He had, from infancy, suffered much from pain in his head, at times severe, and for several months before I saw him it had been intense, rendering him, by turns, delirious.

I discovered that the *cæcum* and *colon* were impacted, constituting the "tumors," and that the condition had been of long standing, evidently impairing digestion, and affecting the brain sympathetically, doubtless leading to the tuberculous meningeal condition in which I found him.

My prognosis was unfavorable, of course; even after having removed—by rhubarb and Epsom salts, with injections of warm water, containing salt, lard, molasses and beef's gall, of each a teaspoonful to the half pint—an enormous quantity of hardened scybala, entirely dispersing the abdominal tumors; for, though it gave him great temporary relief, as I anticipated and warned the parents, the tuberculous symptoms eventually passed on to a fatal termination.

October 24th, 1877, I was called to attend a highly respectable gentleman, about 50 years old, of a fair constitution and excellent habits, who had been in poor health for nearly ten years; having had little appetite, imperfect digestion, a fistula in ano, some cough, and during the entire period what he called a "hardened stomach," his mother having died of a similar affection.

He had been under treatment more or less of the ten years, steadily growing worse up to the time I saw him, when his case had been declared hopeless, mainly from his lungs having become tuberculous, though no matter had yet been expectorated, as appeared. I discovered that what had been regarded as a hardened stomach was really an impacted colon, as was clearly demonstrated by the effects of gentle laxatives, with electricity, which brought away nearly three feet in length of impacted fæces from the colon, entirely removing the hardness, which having been felt most along the transverse colon, had been called a hardened stomach.

This impacted condition of the large intestine had evidently caused, mechanically and otherwise, the indigestion, loss of appetite, fistula in ano, marasmus, pulmonary vomicæ, etc. Its removal gave him great relief, and left the lung disease to lead on to a fatal termination.

On post-mortem examination I found a scrofulous-appearing tumor (*not scirrhous*), on the

duodenum, about two inches below the stomach, with a congested appearance of this portion of the small intestines, all evidently caused by the mechanical impression of the impacted colon on the part. And I have no doubt but that the fistula in ano was the direct and indirect result of the abnormal accumulation, as is often the case.

I was called, January 11th, 1878, by a gentleman, to attend his wife, about 50 years old, in the last stages of what had been regarded and treated as an organic disease of the liver, attended with a tumor of that organ. Her great distress, at the time, was enormous swelling and intense pain in her right leg and foot, for which she desired relief.

I found an impacted colon and cæcum, the latter pressing so heavily (now that she was in bed), upon the right iliac vein and lymphatics as to have caused the swelling and pain, the nerves, of course, being involved, directly and indirectly.

I very much feared that it had produced scirrhus of the pyloric extremity of the stomach or duodenum, as the impaction was evidently of long standing. The ureter of that side was evidently obstructed, as there was intense pain in the right lumbar region, with some swelling.

I gave her fluid extract of dandelion, 4 gm. (ʒj), every morning, and fluid extract of rhubarb and Epsom salts, of each, 4 gm. (ʒj), at evening, directing injections of warm water, with salt, lard, molasses and beef's gall, of each a teaspoonful to 240, cc, (ʒ viij), at evening.

On the third day a large amount of partially softened scybala came away, relieving the right leg and foot of pain and swelling, and the kidney somewhat.

But simultaneously with this, the partially retained scybala, lodging in the descending colon, near the sigmoid flexure, caused a similar swelling, with pain, in the left leg and foot. But two days later, on removal of this retained matter, this also suddenly subsided, as did a pain and swelling in the left lumbar region, from a partial closure of the ureter by the mechanical pressure being thus relieved.

The tumor, which had been regarded as hepatic, had now subsided, except an induration in the pyloric region. And though the patient was now free from pain and swelling, and quite comfortable, she was little more than skin and bones, and died about a week later.

I made an examination, by request of the family, finding, as I had anticipated, *scirrhus* of the pyloric extremity of the stomach and commencement of the duodenum, evidently the result of pressure of the fecal matter in the large intestine passing over it; the kidney of the right side being loosened, congested, and very much enlarged, from pressure upon its excretory duct. The *liver* was normal; and so were all the other organs, except in so far as they were affected by the general marasmus.

I was called, January 26th, 1878, to see a prominent gentleman, about fifty years old, who had been very much constipated for several years, "blood and slime" passing instead of fecal matter, as they informed me.

During the year before I saw him he had run down, suffering the most intolerable tenesmus, and disposition for, without much, movement of his bowels; it having been necessary to draw his water, as I learned, a part of the time.

For twelve weeks before I saw him he had been confined to the house, and at last, more or less to his bed, his case having been regarded and treated, I believe, as dysentery. I did not find positive evidence of any abdominal tumor in this case, as the abdomen was so much bloated it was impossible to diagnose the case by palpation. But suspecting fecal impaction of the colon, I passed my finger into the rectum and found its veins nearly the size of my little finger, and also rectal ulceration.

My diagnosis was an impacted colon. And, with proper remedies, as in the other cases, I succeeded, within two weeks, in bringing away about half a bushel of intensely hardened scybala, which had evidently interrupted micturition, led to the intolerable tenesmus daily, caused the hemorrhoidal congestion and ulceration, and brought him to death's door, as it were, for all these unpleasant complications subsided with the removal of the retained matter, except the rectal ulceration, which was cured by touching, through a speculum, with nitrate of silver. In six weeks he was able to resume his accustomed arduous and responsible business, which he has pursued, with increasing flesh and strength, to the present time, I believe.

An invalid gentleman, forty-five years old, called on me May 13th 1878, from a distant city, of which he is a resident, to consult me in relation to an abdominal tumor, that had been diagnosed as a "loose kidney," as I learned from him, by many prominent physicians, it having been, however, previously poulticed for a long time, preparatory to opening as an abscess. The tumor occupied the right anterior abdominal region, being about the size of two fists, I think. I found that he had been badly constipated for a

long time before he discovered the tumor, which had been sore or tender and painful at times, now rendering him unable to work. My diagnosis was impacted scybala at the junction of the ascending and transverse colon, with possibly an intestinal tumor, as an effect of it, benign or malignant, but probably scrofulous. And with this view, I treated him on the principles already laid down, with laxatives, tonics, etc. On May 31st hardened scybala passed him, leaving the tumor about two-thirds its previous size. And again, June 14th, still more passed, reducing it to about one-third, so that he threw off his bandage or belt, which he had been obliged to wear, and under a laxative and tonic treatment rapidly regained his flesh and strength, enabling him to resume his responsible and arduous labors, which he continued until last autumn, when he again lost flesh and strength, having suspended treatment, and as I have since learned, by the advice of prominent physicians, who regarded the tumor as a loose kidney; he was without treatment through the winter and early spring of 1878 and 1879, except morphine, to quiet pain, which was intense, as I learned, from April 1st till I saw him, May 17th, 1879, when he was very low. Feeling confident that the tumor was connected with the intestine, and probably the result of the impacted colon, and of a scrofulous character, and fully satisfying myself that it had inflamed, suppurated and then contained matter, notwithstanding the high authority and positive assurance of his medical advisers to the contrary, I resolved at once to let the matter out. This I did by introducing the aspirator needle, when, with a very excellent instrument, I drew out 240 cc. (half a pint) of thick, scrofulous appearing matter, affording the patient instantaneous and almost perfect relief from the intense pain from which he had suffered for six weeks or longer. I gave him tonics and alteratives, directed a flannel about the abdomen, a solution of iodide of potassium, 8 gm. (ʒij) to the 30 cc. (ℨj) of glycerin, to be applied to the abdomen morning and evening; and a small poultice to be kept over the puncture, with the hope of keeping it open for the discharge while there was matter.

The matter continued to flow from the puncture for two weeks, and he had improved steadily and rapidly. One week after I drew the matter he was in his garden; and June 13th, being less than a month, he came to see me, a distance of 130 miles; and since July 24th—the tumor having diminished in size, and the hectic, colliquative diarrhæa and night-sweats having entirely disappeared, and his appetite having become excellent, gaining, from June 13th to July 24th, 29 pounds in weight—he has been engaged regularly in his former occupation, that of a railroad engineer, as I am informed.

The tumor may have been *hydatid*, and in that case might have caused the impaction of the colon. But from all the symptoms and circumstances, and from what I have found in other cases, it was probably the *result* of the accumulation of scybala in the colon, and of a scrofulous character, having thus inflamed and suppurated.

I never belived it was a loose kidney, as it was not like cases of that kind that I have examined, in this country and abroad, one of the most interesting of which I examined with the late Sir James Y. Simpson, in Edinburgh, another in this city, and still another in Geneva, a few years since.

Too much care cannot be taken in diagnosing such cases, as upon this depends the treatment or no treatment, and hence, often, the comfort, health, and even life, of the unfortunate patient.

June 1st, 1878, there was brought to this city, and placed under my care, a gentleman from a distant part of the State, 50 years old. He had been for a few months in a gloomy mood, and for the previous few weeks *insane*, and under treatment for it in two of the principal cities of this State and in a distant rural district, from which he was taken to an insane asylum, on a certificate of insanity from two of his attendants, of respectability, I believe.

But as no very favorable prognosis was given at the asylum, and as his friends were not pleased with some of the treatment there, the impression having prevailed, as I learned, that his insanity was from organic brain disease, which some of his symptoms might well have been suspected as indicating, he was brought to me.

I learned that insanity was hereditary in the family; that he would not eat, could not sleep much, and that his bowels had moved but once in two weeks.

Regarding this train of facts and symptoms as indicating incipient impaction of the colon, I induced him to take, freely, pills of aloes and rhubarb, two or three a day, which soon brought away a large amount of hardened fæces, apparently relieving the brain at once. This treatment, together with pepsin, *blood* and *nerve* tonics, with a little cupping in the cervical and lumbar regions of the spine, fully restored him to reason within three weeks.

He gained about twenty pounds of flesh within

a month, leaving the city in good health and spirits, July 5th, one month and five days from the time I first saw him, and up to the last account I have had of him there had been no return of his physical or mental derangement.

It is not probable that the *impacted colon* in this case, had there not been a hereditary predisposition, would have produced insanity. But with it, and a slight spinal irritation, it was sufficient; and its removal effected a cure.

DILATATION OF THE CAVITIES OF THE HEART, WITH PROBABLY SOME HYPERTROPHY, COMPLICATED WITH EXOPHTHALMIC GOITRE, SUCCESSFULLY TREATED WITH DIGITALIS.

BY D. FOSTER MORGAN, M.D.,
Of Clarksburg, W. Va.

Case.—Miss C. D., aged fourteen, called me, July 21st, 1876. This girl has always been very delicate; had a severe attack of heart trouble four years since, from which she recovered. To-day I find her pale, anæmic; pulse at wrist cannot be counted; orthopnœa extreme; the violent action of the heart causes the bed on which she sits—she cannot lie—to shake so perceptibly that it can be distinctly seen across the room, a distance of ten feet; there is constant nausea and vomiting; great prostration exists; she has not slept for more than a week, except a few minutes at a time; appetite entirely gone. She has been treated, so I am informed, with calomel and digitalis in small doses, with no improvement, but she has grown worse for several weeks.

Resorting to the various means of physical diagnosis I find the temperature slightly below normal, pulse irregular, respiration hurried and distressing, amounting to forty-eight respirations in a minute; menstruation suspended for more than three months; slight leucorrhœa. She has dilatation of the cavities of the heart; and why? The heart is weak and feeble; there is stagnation of the vital current; there is congestion of the stomach, liver, kidneys and lungs. There is regurgitation, with valvular insufficiency. There is extreme anasarca; there are cold extremities; the heart's action is so irregular that I cannot count it, even by using a stethoscope; there is almost complete suspension of the urinary secretion; the bowels are constipated; there is chilliness at times; the veins of the surface are at times swollen; the pulse is small and irregular, and I represent it by dashes, dots and intervals, thus—

—— —— ... —— —— ... — — ...

Now, that there is obstruction of the orifice is rendered conclusive, from the following facts: The pulse is small and weak, and the regurgitation necessarily lessens the quantity of blood propelled into the aorta and its branches by the systole of the left ventricle; then the amount of blood contained in the left ventricle at the time of systole is sometimes so much diminished that the radial pulse is almost or quite lost; this condition is partly true in my case, but, in fact, there was a feeble intermittent pulse, yet no one could accurately count it. As regards volume and force, they were affected by an unequal supply of blood from the left auricle to the left ventricle; there was irregularity of the successive beats, due to deficiency of blood to the left ventricle, all of which denotes that contraction of the mitral orifice is in excess, and that regurgitation is in moderation.

In addition to the disorganized left cavities of this girl's heart, the extreme anasarca, dyspnœa, congestion of the stomach, lungs, liver and kidneys, indicate dilatation of the right cavities of the heart as well, which must be necessarily dependent on venous obstruction; and, in truth, I believe this to be true; and why? Because there was turgescence of the cervical veins; because the organs of digestion suffer severely from congestion, arising, as I believe, from dilatation of the right side of the heart; because the secretion of urine was nearly entirely suspended, from a similar cause; because the patient complains of palpitation and smothering; because the heart's action seems violent and strong when the hand is placed over the præcordia; and finally, there is a slight double murmur, which may often happen in dilatation as well as in hypertrophy. There was not a trace of albumen in the urine; the latter fluid was acid.

I considered this case almost hopeless, and so informed the girl's mother, who desired me to do something for her, if possible; and, in fact, I prescribed for her with much misgiving.

Treatment.—I immediately placed her on infusion digitalis, as follows:—

℞. Inf. digitalis, f. ℥ ss
Potass. bitart., gr. cxx.
Every six hours.

I saw this girl again on July 24th, three days after placing her upon treatment, and to my surprise her condition was much improved. Her mother informed me that after taking the first dose infusion digitalis the heart became more quiet and steady; she was enabled to lie in a semi-recumbent position, and slept a portion of the night, and to-day feels much refreshed; she

is eating a little. Urinary secretion partially restored, and even so soon the dropsical symptoms are disappearing. I cannot yet get the true number of pulsations at the wrist nor over the præcordia. I prescribed, as additional—

℞. Ext. bellad., f. ℥ ij
Tr. digitalis, f. ℥ vj. M.
Sig.—Six drops after meals, in water.*

℞. Sol. ferri. et strychniæ, f. ℥ j
Elix. calisayæ, f. ℥ j. M.
Sig.—Teaspoonful before meals.

℞. Emp. bellad. No. 1. Apply over præcordia.

A word as to the belladonna plaster, which many professional gentlemen ridicule. I find it a great quieter of nervous irritability, and of late, in all cardiac difficulties, apply it over the region of the heart; often, it is true, to assist me in diagnosis of these obscure cases, because it seems to me that it controls very well any purely nervous palpitation, and thus enables me to get more truly to the diagnosis of organic disease, if there be any. July 30th, patient still improving. Continued treatment.

August 10th, patient very much improved; the actual pulsation can now be ascertained, and I find the pulse to be 92: respiration much reduced in frequency; dropsy still diminishing. Patient went on improving daily until October 6th, when I omitted all treatment, except inf. digitalis, twice daily, and from this period on the improvement was rapid; the kidneys resumed their normal action, the dropsy rapidly disappeared, the heart's action became more quiet and regular; still there is dilatation and murmur. Menses returned very slightly; leucorrhœa disappeared. October 15th, I resumed tr. bellad. et tr. digitalis, in addition to infusion digitalis. Noon, 15th, placed her on bitter tonics and iron, by which she rapidly improved. She was soon able to be out of doors and visit her friends, and at date of my last note, February 28th, 1877, she has gained much flesh and is doing a considerable amount of housework.

I claim for this case that digitalis is almost a specific in dilatation of either right or left ventricle of the heart, if given in sufficient quantities; and again, from what I know and have seen of hospital practice, the infusion is the particular preparation which gives the most satisfactory results. Now, before treating this case I had not used this remedy extensivly, and had read and heard so much of its cumulative effects that I was really afraid of it; but I can now say, after a much more extensive use of it, that I have never seen the slightest unpleasant symptom, nor have I, so far, met with any gentleman in the profession who has complained of any untoward action of this drug. I discharged this patient Feburary 28th, 1877, and for more than two years I have not seen her; twice in this interval her mother has written me in regard to her condition; once she was suffering from a common cold, and the mother was apprehensive of a return of all her former troubles. The last time she wrote, January, 1879, she said there was some return of the dropsy, the heart was unsteady, etc. I prescribed—

℞. Scoparius, fluid ext., ℥ ij
Fluid ext. digitalis, f. ℥ ij. M.
Sig.—One-half teaspoonful three times daily.

I have heard nothing more directly from the patient, but am credibly informed that her health is good as common.

May 20th, 1879. Since writing the above paper this young lady informed me, through her brother, that she is again in poor health, and there is some anasarca, with many of the old troubles. I prescribed infus. digitalis as before, ordered a belladonna plaster to the præcordia, and gave in addition—

℞. Ext. jaborandi, f. ℥ j
Ext. tarax., f. ℥ ij
Ext. bellad., ℥ ij
Tr. cinchonæ, c., f. ℥ ij. M.
Sig.—Teaspoonful three times daily.

with instructions to report in ten days, and if not better I would see her. I have only learned that she regained her usual health.

* The formula for sol. ferri et strychnia is one I have used for years, and made as follows: I have it put up in quarts, for dispensing:—

℞. Strychniæ muriatis, gr. vj
Acidi muriatici, q. s. M. et take.
Add ℞. Tr. ferri chlor, f. ℥ iij or iv
Glycerin, f. ℥ iv
Aquæ dest., f. ℥ xxiv. M.

SUB-EARTH VENTILATION, AS APPLIED TO HOSPITALS.

BY J. WILKINSON, C.E.,
Of Harvard, Ill.

[At the request of the editor of this journal, Mr. Wilkinson has prepared the following brief description of his method of purifying air and maintaining it at an equable temperature, in its application to hospitals. His plan deserves careful attention from those engaged in hospital construction.—Ed. Reporter.]

My system of ventilation, the symbols of which are S. E. V., was first given to the public in 1874. Its use was, however, mainly confined to milk houses for a period of two years, in

which field it is very profitable and popular. It has since been applied to a variety of purposes, and has fully met the requirements in all cases. The characteristics developed in its use, for tempering and purifying the air of dwellings, have been seen and carefully investigated by numerous intelligent medical gentlemen, and all emphatically assert the opinion that "for hospital purposes it is apparently peerless."

The characteristics of S. E. V. are—

1st. An unlimited volume of atmospheric air may be perpetually supplied to a building, or any number of apartments, at a uniform temperature of about 50° above zero, Fahr.: *i.e.*, by a properly arranged duct, placed at a proper depth below the surface of the earth, say about twelve feet, and about 350 in length, and with a transverse section in proportion to the volume of air to be transmitted in a given time, moving at the rate of about one hundred linear feet per minute, any amount of air required may be transmitted, tempered, purified and delivered.

2d. The air passed through a subterranean duct is found to be peculiarly affected hygrometrically. Carefully conducted experiments, in the use of reliable instruments, have demonstrated the following facts:—

Where the ducts are laid in the virgin soil of rural districts, and they are constructed with an earth bottom, as I construct them, and, if the soil of the bottom of the trench in which the duct is to be constructed is other than clay, it is surfaced with it a few inches in depth, the air from such ducts is superlatively pure; in fact, it is rarely found in nature of an equal degree of purity.

These ducts are found to possess the quality of alternately absorbing from, and giving off moisture to, air passed through them, by which an equable hygrometric condition in the air is maintained. It has been found that when the exterior atmosphere is saturated with moisture, or is at the dew point, air, while being cooled in its passage through the duct, is deprived of its moisture so as to show a difference of from four to five degrees between the wet and the dry bulb thermometers of the psychrometer, the dry bulb showing 61°, in an insulated apartment, and the wet bulb 57°. This experiment was made when the exterior atmosphere was 65° and the wet bulb thermometer showed 65°, indicating that the air was charged to its fullest capacity with moisture.

Again, when the external air was 80°, and there were several degrees difference between the wet and dry bulbs, indicating extreme dryness of the air, the relative difference of four to five degrees was maintained in the building, as indicated by the psychrometer.

These two results, obtained with reliable instruments, under such opposite hygrometric conditions of the atmosphere, prove the positive ability of the subterranean air duct to produce and maintain in the air it supplies an equable hygrometric condition, an all-essential factor among the numerous hygienic requirements of a hospital.

3d. Another remarkable characteristic of this system is the established fact, that by passing air through an earth duct, artistically arranged, an electrical condition which often obtains during the warm season, which precipitates ferments, and produces premature acidification in milk set for creaming, and a coagulation in the milk so dense that it mechanically prevents cream from rising, occasioning a loss of millions of dollars annually, is entirely averted. This loss occurs at a time when the air is in a condition called "muggy," and when electric discharges are frequent and violent, and all breathing animals evince great languor. When the thermal and electrical conditions of the atmosphere described prevail externally, that of an insulated apartment, sub-earth ventilated, is as dry, bracing and buoyant as nature's best.

A device capable of developing and maintaining in the atmosphere the characteristics described cannot but be invaluable, in a sanitary point of view. No other means has ever been devised by ventilating engineers by which such results have been secured, and such adaptability of the atmosphere for human occupancy, especially for the use of persons who are demented or physically abnormal.

I have offered gratuitously to furnish plans for one hospital for each city in the country infected with yellow fever, also full plans and specifications for constructing the tempering and ventilating apparatus. The non-acceptance of my offer by those to whom it has been made, who are identified with the care of the sick in hospitals, has elicited expressions of great surprise by parties who are using sub-earth ventilation in dwellings, that it should not have been generally availed of for hospital ventilation.

In cities and villages, where the soil is liable to be charged with gaseous impurities, close iron pipes are used for the sub-earth air ducts. The pipes may be very light, as they are under no internal pressure.

Some of my devices provide for supplying to and removing from longitudinal shelves within the close pipes, clay and other deodorizers and

disinfectants, by which the purifying influence of the natural earth on the air passed through ducts with earth bottoms is not only equaled, but it is really excelled.

In conclusion, I repeat the offer to gratuitously furnish full plans and specifications for supplying sub-earth ventilation to a hospital building adapted to the system, in any part of the country, also a free right to the use of all my patented devices.

Where a new hospital is required in which sub-earth ventilation is to be used, I will furnish the plans for the same for three and one-half per cent. on the cost of the building, and will embrace sub-earth ventilation in the plans.

It can be applied to any building, but better applied, and at less cost, in new ones.

Medical Societies.

BRITISH MEDICAL ASSOCIATION—SECTION OF SURGERY.

(*Continued from page* 252).

The Section was opened by Dr. L. A. Sayre, of New York, by a discussion of

The Diagnosis and Treatment of Joint Diseases.

He said that he would confine his observations to the joint diseases generally termed scrofulous, such as strumous disease of the ankle joint, white swelling of the knee joint, hip joint disease, and Pott's disease of the spine. All these diseases were generally considered to be dependent on a constitutional dyscrasia. But, Dr. Sayre would ask, if this were true, how was it that many patients, after recovery from hip-joint disease, were ever afterward perfectly well and sound. The family history of many of these cases could be traced back for generations, without any trace of scrofula or any other debilitating affection. In Dr. Sayre's experience, disease of the joint is the result of injury, often very slight. If it be a concussion, an extravasation of blood occurs, which undergoes degeneration and acts as a foreign body, and the cartilage may become loosened and necrotic. Or the injury may be a severe wrench, with laceration of the fibrous tissues and effusion of serum or blood. In either of these instances there is the starting point of a chronic inflammation, especially if the injury be so slight as not to attract attention, because then the proper treatment is not applied at the time when the injury is received. The degenerative processes going on in and about a slightly injured joint produce constitutional disturbance before the local manifestations attract attention; and hence these local manifestations are regarded as the result of the constitutional dyscrasia. Even in strumous subjects, there must be some local injury before disease of a joint can occur. Scrofula will not produce it spontaneously; although scrofula, whether congenital or (as Dr. Sayre believed to be often the case) acquired in consequence of bad hygienic conditions, etc., necessarily develops any disease or accident from which a patient may suffer. In the treatment, the first point to be attended to is the employment of extension and counter extension, carefully regulated so as to readily relieve the parts from pressure, as indicated by the comfort of the patient. The next great element is rest, as complete and perfect as can be given to the parts. Mercury in minute doses is a valuable tonic; and iron, cod-liver oil and quinine may often be added with great advantage. Friction and elastic compression are also useful in certain stages. If the effused fluid has undergone degeneration, it should be removed by the aspirator. If this cannot be done, the joint should be incised, under the antiseptic spray, and washed and dressed according to Lister's method. If caries or necrosis set in and continue to make progress, exsection of the diseased parts is the only remedy.

The subject was discussed by Mr. Owen, of London, Dr. Barton, of Dublin, and Dr. Hodgen, of St. Louis. The latter desired, as far as possible, to settle the difficulty that seemed to exist between Professor Gross and Professor Sayre. Dr. Sayre said that it was utterly impossible that morbus coxarius could be regarded as being derived from scrofulous parents. Dr. Gross said that it was impossible that local injury could produce it. Now, it might appear that those two propositions were very different; and yet to him (Dr. Hodgen) it appeared that they were not greatly opposed; for it seemed that Dr. Gross only insisted that, without a constitutional condition favorable to that particular disease, that particular disease could not occur; while Dr. Sayre said that the existence of a peculiar condition of liability to the disease was greatly increased when the individual was subjected to an accident. Both would accept this proposition: that, if there were not this condition of the system rendering it liable to this particular disease, no amount of force would develop it; and that, when a certain condition of the system existed, a very trifling injury would cause morbus coxarius.

Mr. R. W. Parker, of London, read a paper on

Subcutaneous Osteotomy in Children.

Mr. Parker was attached to the East London Hospital for Children, and would say that, out of a large number of osteotomies performed on children varying in age from three to thirteen, he had never lost a case; and in only one instance had there been any suppuration. This one exception had been a severe case of erysipelatous œdema, which, however, yielded to treatment, and the boy finally made a good recovery. It was now generally admitted that the cause of genu valgum lay in a hypertrophic lengthening of the internal condyle of the femur; and although this fact had long been known, it had never occurred to surgeons to utilize the knowledge for the correction of the deformity. Mr. Parker thought that a special acknowledgment was due to Dr. Ogston for having thought out this treatment, and for his boldness and success in putting it into practice. It was no doubt

the first step in the right direction in the treatment of this disease. Personally, however, he had not adopted Ogston's operation, but the modification of it first performed by his colleague, Mr. Reeves, and described by the latter gentleman, in the *British Medical Journal*, as "subcutaneous extra-articular osteotomy." This operation was a less serious one than Ogston's, and just as effective. He (Mr. Parker) believed that in children the operation could be performed without entering the joint; for the layer of encrusting cartilage, together with its synovial lining, would stretch rather than crack sharply off, as was probably the case in adults. Fortunately for his patients, he had had no opportunity of putting this opinion to the test of the post-mortem room.

A careful paper on

Colles' Fracture

and other fractures of the lower end of the radius was presented by Dr. E. H. Bennett, of Dublin. The author discussed particularly the bearing of comminuted fractures on the disputed question of impaction, showing that the proportion of comminuted to simple fractures is greater than has been admitted by Smith, and that the majority of these fractures present a remarkable constancy in their pattern. He demonstrated that the simple fracture without impaction, and the fracture with impaction only posteriorly, occur as seen in the specimens exhibited by the College of Surgeons; and again, that in comminuted fractures reciprocal penetration of the fragments, contrary to Voillemier's opinion, is the more frequent form of impaction. The following complications of Colles' fracture were shown to be present in the exceptional cases: 1. Necrosis of the lower fragment occurring in the simple fracture; 2. Fracture of the shaft of the radius and of both bones of the forearm; 3. Fracture of the styloid process of the ulna. With reference to the last of these complications, he showed that the fracture of the ulna is probably the result of traction exercised by the lateral ligament of the wrist; that the fractured styloid process unites commonly by ligament, with very trivial displacement. The specimens of the second group presented, in two instances, the features of the "articular fracture" of Gordon; in two, they agreed with the figure of Voillemier, being the reverse of Colles' fracture. The separations of the radial epiphyses were, in two cases, accompanied with the casts of the deformities presented by the limbs during life. The author briefly pointed out the diagnosis of this injury in the living from Colles' fracture; a distinction recently asserted to be impossible. The specimen of united epiphysary separation, if so rightly interpreted by the author, showed that in this instance only, in the entire series, was the relation of the radial and ulnar styloid processes preserved. The fracture of the styloid process of the radius was shown as of interest from its rarity and the small amount of deformity attending its union.

Dr. Meldon read a paper on

Intravenous Injection of Milk,

which was illustrated by five cases operated on by him. The first was one of exhaustion after typhoid fever. The second and fifth were patients in the last stage of phthisis, and in both life was considerably prolonged by the operation. The third and fourth were cases of anæmia, in both of which life was saved by the transfusion of milk. In the three last cases goat's milk was used, to which was added carbonate of ammonia. Dr. Meldon reviewed all the cases on record in which milk had been transfused, and made an analysis, showing the large proportion which have been successful.

In a discussion on

Poro-plastic Splints,

Mr. W. Adams said that in diseases of the spine these seem to be much superior to plaster-of-Paris. Dr. MacEwen, of Glasgow, suggested paraffin jackets. It could be laid on with a bandage, and by pouring cold water over it would in five minutes become as hard as bone. If necessary, the paraffin could be cut off; and it might be taken off at night and put on in the morning. He had, in some cases, kept on such jackets for three or four months, and found them very fair. Its method of application was very easy, and although a little dearer than plaster-of-Paris, it did not break down as often as the latter did. Besides, when a jacket had served its purpose, it could be melted down, and the paraffin would be as good as new.

Dr. Edwyn Andrew called attention to the use of

Medicated Ice.

He pointed out the advantages in certain surgical and medical cases of employing moulded or unmoulded ice; the cold being rendered more effective by being combined with the active principles of drugs, and this combination obtained by freezing various medical solutions. In operations, ice by this means may be rendered highly antiseptic, caustic, or styptic, etc., or these properties may be combined; it may be moulded into various forms, which can be readily handled and applied to parts of the body not easily reached. In medical cases, especially of the throat, stomach, and hemorrhages from internal organs, ice may be thus pleasantly used to relieve symptoms, and convey at the same time medicine and food to the stomach, when the latter would resist them in any other way.

In the sub-Section of Ophthalmology, Dr. J. R. Wolfe, of Glasgow, read a paper on

Obviating the Complications of Cataract Operations.

The risks attendant on operations for cataract were described as being connected with—1. The cornea; suppuration and sloughing of which may occur from various causes. 2. The iris; inflammation and destruction of the eye may arise from injury of this membrane during the operation, or from its subsequent prolapse into the wound. 3. The vitreous humor; which may be lost from the effects of disease, or the use of force. 4. The lens; which may sink or injure some of the structures in its exit, or its *débris* may cause panophthalmitis and collapse. The operation must be planned so as to avoid these risks, and the incisions and other steps must be adapted to the circumstances of each case. In *infantile cataract*, after opening the capsule widely, and allow-

ing the aqueous humor to soften the lens for two or three days, Dr. Wolfe removed it by means of a broad needle. This did away with all necessity for introducing instruments through the cornea for the removal of soft cataracts. In *senile cataract*, he generally performed iridectomy downward, two or three weeks before the extraction, in such a way that there was no risk of the iris being invaginated in the wound. In the extraction, he exposed the eye by means of a speculum, and fixed it with forceps. With von Gräfe's knife he made the incision at the junction of the cornea and sclerotic (including a line more than the third part of the corneal circumference), but did not complete it, leaving a small bridge. In withdrawing the knife, he opened the capsule widely with the point. Substituting his thumb and finger for the speculum, and using a cystotome, he made sure that the capsule was thoroughly opened, and then completed the corneal incision with another knife, and, by gentle pressure and counter-pressure, made the lens advance to the opening. He avoided giving chloroform, if possible. In *traumatic cataract*, when the lens was *in situ*, he made an iridectomy, and extracted it subsequently. When dislocated forward, he removed it without interfering with the integrity of the pupil. When it was dislocated backward, he brought it into the anterior chamber with a needle, and extracted it through a small corneal incision, not interfering with the iris, unless any injured portion of it called for removal.

Tobacco and Alcoholic Amblyopia.

Dr. Hirschberg (Berlin) opened the discussion on this subject. He said that much attention has been devoted to it since amaurosis from smoking was described by Mackenzie; and there has been, both in England and abroad, much difference of opinion regarding the share to be assigned to tobacco in the causation of certain well-known and common cases of failure of sight. While von Gräfe and many of his followers in Germany were drawing out the symptomatic differences between progressive atrophy and benign amblyopia, other observers, especially Hutchinson and others in England, worked at the natural history of the latter class of affections, and established the fact that abstinence from tobacco was followed by cure in most cases. Förster, uniting these two points of view, has given much greater definition to the subject, and shown that tobacco causes a symmetrical defect in the central part of each visual field, which accounts for all the symptoms, and which disappears partially or entirely when smoking is abandoned. The speaker had confirmed and amplified Förster's observations. He maintained strongly that tobacco is the cause of the majority of cases of amblyopia which present the following features: failure of both eyes alike, with nearly central scotoma and corresponding defect of color-perception, without any contraction of the visual field, never passing on to complete blindness, accompanied often by other symptoms of chronic nicotism, and improving or disappearing when tobacco is relinquished. In a minority of cases alcohol appears to be the cause; but the defect of the field in these is thought to be more truly central than in the tobacco cases. In a very few cases symptoms exactly like those from tobacco and alcohol occur without the operation of either of these causes.

In a paper by Mr. H. R. Swanzy, on

Color Blindness,

He stated that the method of Professor Holmgren, of Upsala, has received the greatest meed of popularity. It is conducted by means of colored wools, which are to be sorted according to a system, the two chief tests being by a skein of pale green wool and one of purple wool. By this means the color sense of an individual may be tested in the space of a minute or a minute and a half, while no word need be uttered on either side, and a large roomful of other people about to be tested may look on without vitiating the tests. There is also a method much in use in these countries, upon railways, etc.; it consists in a card with four colored squares, red, green, yellow and blue, to which the correct names are to be given. This is a bad method, for color-blind persons are often able to name colors correctly by virtue of a certain brightness which one color possesses as compared with another. Again, some uneducated people are not familiar with the names of colors, and in this way many seem, with such a test, to be color blind when not so. Holmgren, Cohn, Magnus and Joy Jeffries have been the principal observers of late as to the frequency of color blindness. Donders, Fontenoy and others have also examined large numbers. The percentages given by these observers was, among men, from 2.87 to 6.6. Among women color blindness is extremely rare. The highest percentage for them is given by Dr. Minder at 1.3. Cohn, in 1061 females, did not find one color blind; Magnus only one in 2216; and Joy Jeffries four in 7942. Mr. Swanzy had examined 1320 persons by Holmgren's method; of these ninety were women, and none of them were color blind. Of the 1230 males, eighty-two were more or less color blind, or a percentage of 6.6.

Dr. H. Macnaughton Jones gave his experience with a number of

New Alkaloids

used in ophthalmic surgery. He had found eserin useful in the various forms of corneal ulcer, especially marginal with suppurative tendency; in ulceration with perforation and collapse; in traumatic inflammation of the cornea, and suppurations of the corneal wound after cataract extraction; in mydriatic states, diplopia, asthenopia, aberrations of accommodation; and in glaucomatous states. The preparation used was the hydrobromate. He had employed a solution of gelsemin (six grains to the ounce) for ophthalmoscopic purposes, thus avoiding the inconvenience of the prolonged action of atropin. It sometimes produced marked motor disturbance, and slight conjunctival irritation, but these soon passed off. He had tried sulphate of duboisin in cases in which atropine was indicated, and had found it to have a beneficial action in keratitis, corneal ulcer, and in inflammatory painful states. It had been successful where atropin had to be relinquished on account of the irritation which it produced. He had never met

with an instance of the toxic effect of atropin in ophthalmic practice.

Mr. Vose Solomon (Birmingham) said his experience with eserin had taught him that it was of use sometimes in simple glaucoma, for reducing the tension, while sometimes it rather aggravated the symptoms. It often caused intense pain, and frequently produced conjunctival irritation. Daturin Mr. Solomon found to be as apt to cause irritation of the conjunctiva as atropin was.

Mr. G. E. Walker (Liverpool) thought eserin useful in preventing prolapse of the iris after cataract extraction and in glaucoma. He employed a solution of eserin of four grains to the ounce of water, instilled into the eye, before performing cyclotomy for glaucoma. He thought that the action of eserin disproved Donder's theory, according to which accommodation of the eye for distant objects was a passive action.

Dr. Edwyn Andrew (Shrewsbury) said he found that the use of eserin was liable to cause posterior synechia. He used the alkaloids, not in solution, but in the form of ointment, with vaseline as its base. By this means decomposition of the alkaloid was prevented.

Mr. Swanzy (Dublin) said he had been able to cure a case of acute glaucoma by instillation of solution of eserin. Duboisin, in his experience, had no advantage over atropin, but in some persons readily caused toxic symptoms.

Mr. Story (Dublin) also had had cases of poisoning from duboisin. He had employed the alkaloids in ointment form with vaseline, with satisfaction, for a long time.

Dressings for Injured Eyes.

A paper on this subject was read by Dr. H. Macnaughton Jones, of Cork. He stated that it is of importance to secure rest without either causing pressure on the globe, heating the organ, or preventing the escape of tears or any other secretion. So, also, to resort to the use of cold dressing was often a dangerous step. If employed, it must be sedulously sustained, and its effects carefully watched. Once commenced, it was difficult to relinquish it. The small ice-bladder or the piece of linen must be changed occasionally. Nevertheless, it often became heated, and was a source of danger. The cotton-pad was heating, and required a skillful hand in applying it. It imprisoned the secretion often adhering to the eyelids. In January, 1877, having seen recorded Dr. Levis's plan of dressing, in the PHILADELPHIA MEDICAL AND SURGICAL REPORTER, Dr. Jones determined to try it, and since had pursued it almost entirely, especially after cataract operations. He could strongly recommend it. He quoted the description there given. "A few semicircular pieces of black silk are placed on the upper lid, to stiffen it, and cause it to act like a splint, and then a straight piece of the adhesive plaster is superposed from the root of the nose to the cheek. The other eye is also closed the same way. This—much lighter and cooler than the cotton packing usually placed over the eye—allows all secretions, which are so apt to cause conjunctivitis, to drain away from under the lid, and enables the surgeon to look at the eye and instill atropia without moving the dressing. At the same time, it perfectly protects the eye, which cannot be opened because the stiffened upper lid will not allow itself to be raised." Dr. Jones used a few pieces of isinglass adhesive plaster (Seabury & Johnson's). The lids being closed, from the nose to the external angular process, smoothly and lightly over the upper eyelid, a few more were then placed on the lower eyelid, and then some pieces were brought from the upper to the lower lid, and held in place by a few extra transverse strips. The patients liked the dressing; the upper lid acted as a splint to the wound, and it had all the advantages described above.

The sub-Section on Otology was opened by Dr. Cassells, of Glasgow, who, in a brief address, referred to the recent progress of this branch, and in concluding nominated Dr. Laurence Turnbull, of Philadelphia, who was present, to be Chairman of the section. This nomination was unanimously carried, and Dr. Turnbull took the chair and replied in an address of thanks for the honor.

Papers were read on throat deafness, by Dr. E. Woakes, followed by one on

Intra-tympanic Injections,

by Dr. Cassells. The result of his investigation had been to convince him that the use of intra-tympanic medication of the diseased tissues of the middle ear was without value separated from the act of inflation, by which the introduction of the fluids into the tympanic cavity was effected; and he had therefore abandoned their use for the last seven years. The good results which were obtained, in his opinion, by those injections, where they were obtained at all, were due to the inflation of the tympanum by the air contained in the fluid, or driven in along with it, and not to the medicated fluid itself. It was not possible to break up adhesions, dissolve mucus, and generally restore the mobility of the tissues of the ear by medicated solutions, such as of zinc, copper, iodide of potassium, chloral, and chloride of sodium, while these tissues themselves, and the mucus contained in the tympanum, outside of the body, were found totally insoluble in such solutions as liquor potassæ, absolute alcohol, and nitric and muriatic acids.

Among numerous other papers presented to the sub-Section, was one on

Tinnitus Aurium,

by Dr. Laurence Turnbull, Philadelphia, giving the statistics of 166 cases in which it appeared as a prominent symptom. Mr. W. D. Hemming also read a paper on the subject. In the discussion which followed electricity was generally recognized as useless, while hydrobromic acid has a positive value.

—The celebrated London physician, Dr. Mead, is said to have quarreled on some point of precedence, and fought a duel, with Woodward, the scientific geologist, in the archway of Gresham College, Bishopsgate, where two sculptured figures still commemorate the feat. As Mead stood over his fallen antagonist, with drawn sword, he said, "Will you beg your life?" "Never!" was the unvanquished and ready answer; "Never, till I am your patient, Doctor!"

Editorial Department.

Periscope.

Successful Management of Diphtheria.

In forty-five cases of diphtheria, Dr. S. S. Boyd, of Indiana, had but one death. He thus describes the method he pursued (*American Practitioner*, July):—

When called to see a patient, if I found that his bowels were moved daily, which was generally the case, I administered no purgative. When I thought the bowels should be evacuated, I ordered sulphate of magnesia or bitartrate of potash in small doses, until mild catharsis was established. Four grains of sulphate of quinia and sixty drops of hydrochlorate of iron were given after each meal. I prepared a large swab, made of a strip of muslin raveled on one edge, and so wrapped around the end of a stick or whalebone that it made a soft brush, but four times as large as we usually find camel's hair brushes. Dipping this brush in the tincture of muriate of iron, it would absorb half a drachm of the fluid. Then depressing the tongue, I gently pushed the swab back between the tonsils until it touched the back wall of the pharynx. This caused a contraction of the muscles of the fauces, so as to drive the fluid into every part of the pharynx. This simple operation I performed only morning and evening.

In those cases where there was much fetor of breath the patient was ordered to gargle the throat frequently with whisky and carbolic acid, ten drops of the latter to an ounce of the former. I also advised them to swallow a little of the same each time they used the gargle. In two of the more serious cases I ordered an ounce of whisky with two drops of carbolic acid, three times per day. In my own case, out of respect for my medical friends who visited me, I took four or five fifteen-grain doses of chlorate of potassa.

Paralysis and Impotence, from Spermatorrhœa--Cure.

In the *Canada Medical Record*, Mr. C. R. Roberts, of London, Eng., gives the case of a man 35 years of age, married, three children, with complete loss of motion in the lower limbs. No cause for the paralysis could be found until, on examining the urine with the microscope there appeared to be spermatozoa floating in it, and this further examination placed beyond question. Following up this clue I elicited that he had for several months experienced an almost constant desire for sexual intercourse, with a gradual diminution of power and an increase (until they became of nightly occurrence, and frequently in the night) of seminal emission while asleep. There was no priapism, and the testes appeared normal. He is a married man and the father of three living children. His wife states that for a long time he has been always wanting to, but quite incapable of, discharging his marital duties. Now what was to be done in a case of this kind, which appeared to be hopeless? I felt inclined to despair, but remembering a case which occurred to me at Salisbury, I determined to take him in hand. He was ordered to be well purged twice a week, with calomel and colocynth, at bedtime, and sulphate of magnesia in the morning; galvanism was applied night and morning to the back and legs; he was held up every morning in a bath, with his feet in warm water, while the cold shower bath was administered for two or three minutes, afterward increased to five, and eventually to fifteen minutes, and was given thrice daily five minims of tincture of nux vomica and five minims of the tincture of sesquichloride of iron, in an oz. of water (this dose of each was after an interval doubled, then trebled and eventually quadrupled, and this larger quantity he took daily without any intermission for twelve months and upward); all attempts at sexual intercourse were strictly forbidden, and he was ordered as good and as nourishing a diet, with stout, wine, etc., as their circumstances would permit. This plan of treatment had a most charming and satisfactory result; in a few weeks he was enabled to get out of bed, and holding by the bed hobble round it; he became able to walk with crutches, then with one and a stick, then with two sticks, and for some weeks before I left, in February, 1879, he walked down to me many times, a distance (both ways) of nearly seven miles, without any assistance whatever, although he always carried a stick. The spermatozoa disappeared entirely from his urine, and he was allowed and enabled to perform his marital duties in moderation and with success.

Chloral in Vomiting in Pregnancy.

In the *Virginia Medical Monthly*, Dr. J. H. Scarff reports four very successful cases of vomiting in pregnancy cured by chloral hydrate. We quote two of them:—

Case 1.—Mrs. S., fifth pregnancy; nausea and vomiting incessant from the beginning of her last pregnancy until I saw her, October 16th, 1877. I ordered for her cerium oxalate and bismuth subnitrate, which gave her temporary relief. In a few days she sent for me again, when I found her condition most deplorable. I prescribed for her one remedy after another, with little or no success. I concluded to give her the chloral, and ordered for her forty grains, to be prepared in a mucilaginous mixture. I instructed the nurse to inject one-half per rectum, which was done at 8 P.M. She slept an hour or two that night, but nausea and retching returned again in the morning. Chloral was repeated, and nausea ceased for awhile during the day, allowing her to retain a small quantity of milk and brandy. Twenty grains of chloral were repeated at night, and she slept all night. I saw her early the following morning, and notwithstanding she said she felt very well, I repeated the chloral, and am happy to state I did not have to give her another dose of medicine until she was confined, April 6th, 1878.

Case 2.—Mrs. M., of Washington, primipara, while visiting her mother in this city consulted me in regard to morning sickness, or indigestion, as she termed it. I questioned her as to the possibility of her being pregnant, but she did not know, as it was nearly a week before the time for a recurrence of the catamenia. I prescribed for her tincture of calumbo and lime water, which benefited her for a few days. I finally changed from one remedy to another, her case growing from bad to worse, until the vomiting became incessant. The success in Case No. 1, by the use of chloral, tempted me to try it again. Twenty grains of chloral in solution were injected into the rectum, and this treatment was continued night and morning until four doses were taken, which resulted in a complete cure.

The Catarrhal Form of Diphtheria.

Various cases of this form of diphtheria are reported by Dr. W. J. Fairfield, in the Detroit *Lancet*, August, 1879. He says of it—

The patient, with the exception of some degree of prostration and weakness, is usually recovered by the third or fourth day.

This form is liable to be mistaken for a simple pharyngitis, where there are patches of exudation. But in a simple pharyngitis the patches of exudation are accumulations of a modified form of the natural secretion around the mouths of the follicles, and dip down into the cavity of the follicles. The secretion is soft and semi-fluid, pultaceous, and almost wholly mucous. In the catarrhal form of diphtheria the patches are not confined to the mouths of the follicles, but are generally found on the most prominent points of the tonsil or part where they are formed.

Sometimes there is slight erosion of the mucous membranes of a tonsil or other part, and the yellow suppurating surface presented by the ulcerations may be mistaken for a diphtheritic patch, but the border of the ulcers can be plainly seen, as well as the loss of substance, which rarely occurs, if ever, in the catarrhal form of diphtheria.

I feel that it is dangerous to recognize diphtheria only in its severer and plainly marked forms, for by so doing suffering may be extended and life sacrificed.

The following facts I present you as establishing a catarrhal form of diphtheria; facts which have been brought to light by well known and competent observers:—

1. It is prevalent in connection with an epidemic of typical diphtheria.

2. Occasionally germs from this form will produce croupous diphtheria.

3. Sometimes it precedes the more severe form, continuing three or four days and then merging into the croupous form.

5. Traces of albuminuria which have been found to occur in the majority of severe cases, have been found in some of these.

5. Microscopic examination of the exudate reveals the micrococci and bacteria termo, which are always found in diphtheritic membrane.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——The causes, symptoms and treatment of lacerations of the cervix uteri are detailed by Dr. A. Reeves Jackson, in a reprint from the Chicago *Medical Journal and Examiner*.

——Dr. John Eastman, in a reprint from the *Transactions* of the Indiana State Medical Society, gives a careful summary of the rules and precautions to be observed in excision of the knee joint, with illustrative cases.

——In a paper on statistics of placenta prævia, collected from the practice of physicians in the State of Indiana, Dr. Enoch W. King, of Galena, Ind., presents a series of results, valuable for comparison with the figures of other writers.

——It is satisfactory to record the disenthralment from their delusions of the honest disciples of Hahnemann. In a pamphlet before us, by Dr. H. M. Paine, of Albany, he closes with the significant words—

"Inasmuch as the *Organon* [of Hahnemann] is considered the only correct exponent of homœopathic principles, all that portion bearing on the theory of dynamization should no longer receive the support of the homœopathic medical profession."

——Lippincott's Magazine for October has a pleasing variety of entertaining articles and handsome illustrations. One of the contributions, "The Double Life of Martin Staples," is a curious psychological study, in the style of some of Poe's writings. If not founded on fact, it has great verisimilitude. It portrays a not uncommon form of epileptic mania, in the attacks of which the patient believes he lives an entirely different life and yet is the same, himself and yet another.

——Parts III and IV of "Photographic Illustrations of Skin Diseases," by George Henry Fox, A.M., M.D., the earlier numbers of which we noticed in the Reporter, July 5th, have appeared. They contain specimens of fibroma, varicella, zoster, eczema, leucoderma, chromophytosis and favus. These plates are taken from life, and colored with great accuracy. They have met immediate recognition from the most distinguished dermatologists. Published by E. B. Treat & Co., 805 Broadway, New York. Price $2.00 per part.

——"Vegetarianism the Radical Cure for Intemperance," is the title of a pamphlet of 79 pp., by Harriet P. Fowler (New York, M. L. Hol-

brook & Co.). Her argument is that meat causes intemperance, by its absence of carbonaceous properties, and by its stimulating effect upon the stomach and nervous system. The assertion is reiterated that those whose diet consists chiefly or wholly of vegetables do not crave alcoholic drinks. Nothing is said of the Irish or Scotch peasantry, who are lucky if they taste meat once a week, but who are always eager for their fiery whisky; nothing of the peasantry of the south of Europe, who also rarely touch meat, yet who look on wine as a necessity. For ourselves, we believe the exact contrary of the author's theory can be maintained with equal plausibility.

——Certain writers of the present day take great delight in asserting that the present, especially the present American, generation is weaker, smaller and more subject to a variety of ills, than were its ancestors. Dr. C. Fayette Taylor is one of these. In a paper read before the New York Odontological Society, on "Emotional Prodigality," he has much to say of the weakness of American girls, their nervousness and emotionalism. He thinks they are taught too much, fondled too much, urged too much. He exclaims—

"The result is deplorable. With the mind thus forced to an unnatural activity, the emotions strained up to the highest tension, at such an important period, what chance has the body to attain a perfect growth or the various functions to be properly developed? Hence we see that generation after generation becomes smaller and smaller, until nature ceases to reproduce its own, and new blood has to be brought in to keep the race from dying out. Take a walk on the avenue of a Sunday afternoon and witness the large proportion of diminutive men and women whom we shall meet. Then tell me if I have overdrawn the picture."

We think he has, to an absurd degree. There is positive evidence that the present generation is neither weaker nor smaller than its predecessors, but the reverse; and from considerable personal observation we maintain that American school girls are as healthy, cheerful and handsome as any to be found in the world.

——The same writer, in a reprint from the Boston *Medical and Surgical Journal*, makes some instructive observations on the mechanical treatment of diseases. He observes—

"It is absurd to speak of 'an instrument for hip disease.' There can be no one complete instrument for hip disease. There can only be instruments calculated to answer the indications present at some stage of hip disease. The surgeon who treats disease of the hip-joint by a method calculated to fulfill but a single indication, whether by gypsum or other bandages, sand bags, splints, or what not, fails, in my opinion, in his conceptions of the elements of the case, as he surely will fail of securing the best attainable results."

BOOK NOTICES.

A Treatise on Hygienic and Public Health. Edited by Albert H. Buck, M.D. Volumes I and II. New York, Wm. Wood & Co.

This handsome work, in two large volumes, of nearly eight hundred pages each, is in size and type uniform with Ziemssen's *Cyclopœdia*. The editor states that it is in some measure intended to take the place of the first volume of the original of that series, which is concerned with public health, but treats the subject from a point of view so entirely German that it would be of comparatively little value in this country.

The volumes are a collection of monographs on separate subjects relating to public health, composed by American writers with special knowledge of the different branches they handle. It is sufficient to say of these contributors that they include many of the most eminent sanitarians in this country, and the productions they have furnished give evidence of attentive and careful study, quite equal to that to be found in any foreign work in any language.

The scheme of the work is to divide the general subject into four parts, treating respectively of individual hygiene, habitations, occupations and public health proper. These are preceded by an introduction on the causes of disease and the jurisprudence of hygiene.

Individual hygiene begins with the newly born infant, takes it through its nursing months, discusses the diets suitable to it, both as substitutes for mother's milk and when it commences independent eating, and carries it up to the age of schooling. This section is written by Dr. A. Jacobi, of New York. The subjects of food and drink, by Dr. Tyson, of Philadelphia; and of drinking water, by Dr. Nichols, of Boston; give the physiological chemistry of these aliments as far as known, and the cautions necessary in their use. The chapter on physical exercise, by Dr. Hall, of New York, contains, among other interesting matter, some judicious instructions on training, and the wisest rules for the development of muscle, which are very timely just now. This part closes with a chapter by Dr. Van Harlingen, on the care of the person. It is at once entertaining and sensible.

The subject of habitations is considered first with reference to the surrounding soil and water, including drainage, soil pollution, the

ground water, sewerage and the selection of a site. The writer is Dr. William H. Ford, at present the President of the Board of Health in this city, and a most competent authority. The atmosphere, which is next considered by Dr. Lincoln, of Boston, includes not the air merely, but meteorology, climate, ventilation and heating as well. Numerous diagrams and cuts are inserted in these articles, which facilitate the explanations of the authors. The part closes with a chapter on hospital construction, by Dr. Francis H. Brown, of Boston.

The portion on occupations discusses the relative dangers and advantages which they present, from a sanitary point of view, and then proceeds, in separate chapters, to discuss the hygiene of camps, of the naval and merchant marine, of coal mines and metal mines. Camp life is contributed by Dr. Charles Smart, Asst. Surg. U.S.A., and the article on the naval and merchant marine by Dr. Thomas J. Turner, Med. Director, U. S. N. Dr. Turner is an experienced surgeon, and has long made naval hygiene a specialty, but the securing his pen for the hygiene of the merchant marine, when there are so many surgeons of the United States Marine Hospital Corps who have distinguished themselves in sanitary studies, is an injustice to that corps which Dr. Buck should not have committed.

The last part, on public health proper, treats on the causes of infant mortality, the registration and investigation of vital statistics, the methods of detecting adulterations of food, the various offensive trades and processes which are considered public nuisances, quarantine, the prevention of smallpox and syphilis, the various disinfectants and their uses, sanitary associations in villages, and the hygiene of schools. A well prepared index closes the work, and many of the monographs have appended to them tolerably complete bibliographies.

It will be seen that the ground is well covered by this treatise, or collection of treatises, and one cannot doubt but that much good will be accomplished, both in and out of the profession, by its circulation.

Transactions of the Thirty-fourth Annual Meeting of the Ohio State Medical Society, June, 1879. Columbus, Ohio.

Transactions of the Medical Association of Georgia, 1879. Atlanta.

At the Ohio meeting the address of the President, Dr. B. B. Leonard, was on State government and the medical organization. He touches to the quick the need of an anatomical law in that State. Speaking of it and allied matters, he remarks—

"Strange as it may seem, gentlemen, much of the opposition given to the progress of our calling comes from the clergy, those who ought to be our friends and allies. Those whose grave duties look to a cure of the evils in the soul ought to aid us who are seeking to alleviate the ills of the body. Many of these men, if not openly our enemies, are certainly not our friends."

If Dr. Leonard had thought about the history of the neighboring State of Pennsylvania, he might have concluded that the doubts entertained by the earliest settlers of that commonwealth as to the propriety of making a business of teaching religion have some foundation. Dr. Roberts Bartholow contributes a short paper on the treatment of consumption, including climatic and therapeutic resources. The preservation of good eyesight and the use of spectacles is the subject of a paper by Dr. J. H. Buckner. Other original papers are by Dr. Kinsman, on hog cholera; by Dr. J. C. Reeve, on mind anæsthesia; by Dr. P. S. Conner, on the plaster-of-Paris roller in the treatment of club foot; on tubercle, by Dr. H. J. Herrick; on sanitary laws, by Dr. Geo. E. Walton; on glaucoma, by Dr. S. C. Ayres; and on the metric system, by Dr. J. F. Baldwin.

Of the papers in the Transactions of the Georgia Association, we have on previous occasions referred to those on quarantine, by Dr. Le Hardy, and on yellow fever, by Dr. Westmoreland, and the effect of tobacco on the eyesight, by Dr. Calhoun. Other original papers are by Dr. H. F. Campbell, on uterine flexions; on the toxic effects of bromide of potassium, by Dr. C. H. Hall; on reflex excitability, by Dr. A. W. Griggs; traumatic tetanus, by Dr. A. R. Taylor, etc.

The address of the president, Dr. J. T. Johnson, of Atlanta, is, as he says, upon a topic as old as the profession itself, though for all that not a venerated one—the poverty of physicians. We have read closely, in hopes that he had discovered a specific for this chronic malady of the pocket, but, alas! we hoped in vain. One after another he takes up the alleged specifics—business habits, cash payments, black lists, prompt collections, etc., but pronounces them inert, or nearly so. Finally, he has recourse to philosophy and resignation, and concludes with the wise though disappointing information that—

"Wealth can bring no contentment more serene than the consciousness of duties well done; and, at last, there is no happiness more complete than the sweet memories of a life well spent."

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00

115 South Seventh Street,
PHILADELPHIA, PA.

SOME POSSIBLE EXPLANATIONS OF MIRACULOUS CURES.

The acute historian, A. W. SCHLEGEL, makes the profoundly correct remark that no advance in scientific culture, no increasing perfection of social order, is a guarantee against occasional reversions to superstition and fanaticism. It is indeed true, as Pliny observes in his *Natural History*, that the more readily miracles are received by foolish and superstitious persons, "*simplices et religiosi*," the more numerous they will be reported to be; but at all times there are dispositions with a bias to the supernatural explanation of facts, and an inborn tendency to mysticism, who prefer to accept on faith rather than to explain by knowledge.

The domain of medicine has always been a favorite one for the dealers in wonder-works, and it remains so to this day. This summer just past has illustrated it anew. The secular and religious Protestant press have chronicled quite a number of cures of chronic diseases, the result of prayer. We noted that the camp meetings were more efficient in this direction than usual. In France, the shrine of "Our Lady of Lourdes" has attracted thousands of pilgrims and performed many cures. We take from "*Le Monde*," a paper published in Paris, a description of one of these pilgrimages, now-a-days no longer performed with staff in hand and sandals on feet, but in the more commodious plan of traveling devised by worldly men. The writer says:—

"The six hundred sick and suffering took their places in the train with some trouble. The hospitality and kind offices of the Poitevins were admirable. More generosity or delicacy was impossible. A person deprived of sight for several years was suddenly cured on the way, while the chaplet was being recited for the sick. * * * The five trains have safely arrived. A train from Carcassonne and another from Bordeaux are expected. We went straight to the grotto, where the cures were at once manifested. The sick who were cured left their crutches at the grotto. All the pilgrims express feelings of the greatest faith, hope and gratitude."

As the Virgin of Lourdes, has, we are informed, never been officially recognized by the Papal authorities, a member of that church has it open to him to accept or reject the supernatural character of the cures there performed. That they are real and numerous, there seems no room for doubt, and the same must be said of some of those previously referred to as recorded in this country.

It is strictly within the limits of medical science to examine and discuss these facts; indeed, the physician who would refrain from doing so or would object to approaching them, is either timid or does not appreciate the duties of his profession.

Assuming them, then, as actual facts—and we repeat, there exists no reasonable doubt about them—we should inquire, first, whether they are capable of explanation by known laws of the mental and physical organism.

The reply to this is that the influence of the mind on the body through expectant attention, fixed belief, and confident trust, is powerful enough to effect the cure of many functional, nervous and mental diseases. These include all forms of hysteria, and many phases of epilepsy, paralysis and lameness. In a vast number of diseases which present obstinate and serious symptoms, but all traceable to some neurosis as a

starting point—a condition of affairs by no means infrequent, as for example in some forms of dyspepsia, and neurasthenia—the removal of this neurosis would be followed by a disappearance of the whole train of sequent evils.

It has been further amply proven that processes of repair are greatly influenced by expectant attention and confidence. This has been shown over and over again in the healing of ulcers and wounds. There is as much and as good evidence that scrofulous sores were repeatedly healed by the royal touch as for any fact in history.

As the emotions of doubt, fear and despair are almost certain to jeopardize a patient's chances, so the contrary emotion of hope greatly improves his condition. As FEUCHTERSLEBEN forcibly remarks, in his *Elements of Medical Psychology*, "Hope preserves the principle of duration when other parts are threatened with destruction, and is a manifestation of the innermost psychical energy of Life." When Hope is exalted into Faith, into that perfect faith which casts out fear and knows not doubt, how much more potently must it work on the economy? In truth, we are hardly ready to set any limits to the action.

By the explanations here suggested a very large number of such cases can be rationally understood. To these must be added the percentage of simulated or artificial diseases, a certain number of which are sure to be found in every large hospital. It is almost a mania with some people to pretend to be sick; and it is part of the trade of others to entertain a disease which they could get rid of soon enough were they really to wish it. Some of these cases are deliberate malingerers, others are so out of a desire for sympathy or for notoriety. They are found in all classes of society, and are sure to come to the front in incidents like those we are considering, where some capital is to be made.

Thirdly, there must allowance be made for exaggerated statements, both on the part of the patients and the observers. Without casting doubt on their honesty and good intentions, the very circumstances surrounding all these miraculous cures forcibly incline both parties to hasty and overdrawn accounts. They both desire to magnify as much as possible the agency of the supernatural, and hence are apt to color deeply the disease and its dangers.

These are the rational explanations which all should be willing to recognize and apply, as far as they will go. They should allow the Horatian maxim, not to call in the god unless the crisis requires his aid. Whether all the miraculous cures can thus be explained away, we do not pretend to say. As no law of nature is absolute, we should be prepared for exceptions to all of them; and it is not the truly scientific frame of mind to deny the *possibility* of any occurrence; we are only arguing for that first maxim of inductive science, that where several explanations of a given occurrence are possible, we should always prefer that which is simplest, most easily understood, and most in accordance with other similar occurrences.

Notes and Comments.

Increase of Consumption in Southern Latitudes.

We have on a previous occasion noted the steady increase of deaths from phthisis among the natives of the Madeira Islands, Naples, Florida, and other warm health resorts. The New Orleans *Picayune*, August 5th, calls attention to the same fact in that city. It says—

"The attention of our physicians might profitably be devoted to the consideration of the conditions which have caused the large increase in this city of mortality from consumption. Not many years ago this disease was comparatively rare in this latitude. The mild and equable climate was considered beneficial for persons with consumptive tendencies, and many came from colder latitudes to take refuge in New Orleans from the rigors of northern winters. Last week's mortality report records the death of twenty-four persons from consumption. At this rate the mortality would, for the year, be in excess of that from all fevers combined."

It is probable that the fact here recorded of the many consumptives who pass the winter in New Orleans explains the increasing deaths from the disease of the natives; for it may be believed to be natives only, and not visitors, whose deaths were recorded in July.

Therapeutical Notes.

IODIDE OF ETHYL IN ŒDEMATOUS LARYNGITIS.

In the *Annales des Mal. du Larynx* Dr. Capitan records a case of œdema of the glottis which occurred in the course of a pulmonary disease after catching cold. All the dangerous symptoms of suffocation, dyspnœa, and pain in swallowing, occurred, but were successfully combated in a few days by the inhalation of ethyl iodide.

TINCTURA FERRI PERCHLORIDI IN DIPHTHERIA.

Dr. James Carmichael writes to the Edinburgh *Medical Journal*, August: "I was formerly in the habit of frequently applying hydrochloric or carbolic acid or other strong solution to the throat; but of late I have been content with a single, or much less frequent, recourse to these strong local applications, or even with their entire abandonment, trusting solely to the tincture of the perchloride of iron, administered in very frequent doses—10 to 15 minims in ℥ ss. of water every hour, or even oftener. When taken thus, I believe the drug exercises sufficient direct action on the throat during deglutition to enable us to dispense entirely, in the great majority of cases, with any other local application whatsoever."

ARSENIC IN ASTHMA.

An Italian physician, Dr. Martelli, reports great and immediate benefit in the paroxysms of asthma, by the hypodermic injection of a few drops of Fowler's solution—one part to two of water. Dr. Berkart, in his late monograph on asthma (noticed in the REPORTER a few weeks ago), quotes favorable opinions of its effects given internally and by fumigation; but says nothing of its subcutaneous use.

THE CHLORIDES OF LITHIUM AND PLATINUM AS NERVINES.

The chloride of lithium has been used lately by Dr. S. Weir Mitchell, of this city, as a nervine tonic in epileptic excitement. The chloride of platinum was some years ago advocated by Huss (Köhler, *Spec. Therapie*, I, p. 656). The operation of these drugs seems uncertain, or, at least, has not yet been clearly defined. It would be interesting to have reports upon them.

The Treatment of Diphtheria and Anginous Paralysis.

On this subject Prof. Hardy, of Paris, remarks, in one of his lectures, that cure is the rule, and the cure generally supervenes of itself, the *rôle* of the physician being to assist it; to do this, one should raise and sustain the strength of the patients, by means of iron, quinine, coffee and nourishing food. In some special cases one may have to interfere, by the œsophageal tube, to assist deglutition when it cannot be made without fatigue or danger by the patient. In cases where the paralysis of the soft palate or of the pharynx does not improve rapidly under the above treatment, have recourse to electricity, in the form of interrupted currents, or still better, under the form of the continuous current, employing remedies which have a special action on the muscular fibre, such as nux vomica; use at the same time sulphurous baths, which may be given several times a week.

Prevention of Cystitis after Cantharides.

M. Guyot Dannecy, as quoted in the *Practitioner*, recommends the incorporation of a certain quantity of carbonate or bicarbonate of soda in place of powdering blisters with camphor, as is generally done. For this purpose he mixes equal parts of carbonate of soda and cantharides powder, and then spreads the mixture upon the plaster. The blister is fixed by strong pressure with the palm of the hand, and is covered with a layer of oiled silk. The vesicant acts as rapidly and as surely as one made with the simple powder of cantharides without any admixture with other substances. The experience of the many years during which it has been in use at the Bordeaux hospitals tends to show that the addition of the soda salt is a much safer preservative than camphor against those accidents to the neck of the bladder which occur so frequently after the application of blisters, whether or not they have been previously camphorated.

Extract of Beef by Expression.

A variety of succus carnis or meat juice is extensively used in St. Petersburg by invalids and infants, in the place of raw meat. It is said to contain all the constituents of the latter in solution, being prepared by expressing fresh beef by means of hydraulic presses, and filtering. It is a clear, red liquid, having an acid reaction, a pleasant taste, a specific gravity varying betwen 1.031 and 1.037, and mixes clear with a little hydrochloric acid, but is coagulated by a larger proportion of the latter, and also when boiled. It is not rendered turbid by acetic acid and sodium chloride, and was found to contain albumen, gelatin, sugar, creatin, inosinic, lactic and carbonic acids and oxyhæmoglobin. The ashes contained potassium chloride, sodium chloride, and phosphate and sulphates of calcium, magnesium and iron. Whether any of the "beef extracts" in the American market are prepared in this manner we cannot say, but it would seem to be an excellent method.

Ancient Forms of Nervous Disease.

In drawing the broad distinction that he does, in a letter in this number, between physical and psychical nervous diseases, does Dr. George M. Beard write in the full light of modern pathology? Does not that teach that *all* disease is physical? Is not the difference which he points out between the two forms of nervous disease merely one of expression and interpretation, as he himself intimates in the last sentence of his quotation from the *Quarterly Journal of Inebriety?*

Both the soundest theologians and the most skilled physicians of the Dark Ages maintained that the nervous maladies so prevalent then were physical, more than mental. St. Augustin says the subjects of them were generally of feeble bodies and subject to bile and humors; Cornelius Agrippa, that the "possessed" were weak and melancholy persons; Pomponatus, that they only needed medical treatment, and could be cured by it; and the historians of medicine are full of further evidence to the same effect.

The Cooling Treatment in Measles.

This plan of treatment was strongly advocated years ago in the Reporter, by Dr. Hiram Corson, and it is gratifying to observe that in the Atlanta *Medical and Surgical Journal*, for September, Dr. E. A. Cobleigh reports a number of cases most successfully treated by it. He concludes his article by saying—

"Of the cases mentioned, nearly all complications spoken of arose in persons who had been first medicated with hot teas, hot rooms, hot beds, hot baths, starved and purged, according to popular custom. On commencing a radically opposite plan, they improved as by magic from the start, and without exception expressed or manifested immediate relief from what had previously been torture. In most cases the eruption was extensive while using the cold to interior or exterior or both; and in a few instances it was excessive, showing beyond controversy—and one fact is worth a hundred unsubstantiated theories, however plausible or scientific—that cold does not repel the cutaneous manifestations of rubeola or any other exanthem, where nothing else interferes.

"If physicians who are afraid of cold in measles will only try it once, they will lose all fear of the method; will be happily disappointed at the prompt recovery of their patients; will find not only their sufferings mitigated, but actually shortened as well, though I do not claim abortive powers for the antipyretic plan of therapeutics; will meet fewer troublesome complications and almost no pathological after-conditions."

The Dangers of Improved Habits of Life.

In one of the most pleasing of George Sand's novels, *Le Meunier d'Angibault*, she records the singular observation that when a French peasant, brought up on a spare and chiefly vegetable diet, enriches himself sufficiently to indulge in meat every day and the other comforts of a *bourgeois*, it nearly always kills him in a very few years. A similar observation is made by Dr. Henry Gibbons, Jr., of San Francisco, in a late paper, entitled, "Notes on Hospital and Private Practice." He says:—

"The conclusion has forced itself on my mind, that the transition from a rugged mode of life, with simple fare and much exposure, to the comforts and luxuries of a higher civilization, is a hazardous experiment on the human constitution. We observe it particularly in the native Indians, who, when transferred from their wild life to the domestic service of the white population, become remarkably sensitive to the causes of disease, and when taken sick, succumb almost invariably and without exhibiting any power of resistance. When I find an Indian in the hospital ward, I very generally expect him to die, particularly if he has the slightest pulmonary disease. The same observation holds good, though not to the same extent, in regard to native Californians of mixed Spanish and Indian blood."

Correspondence.

The Prevalence of Nervous Disease.

Ed. Med. and Surg. Reporter:—

I find, on my return from Europe, a copy of your editorial (July 26) on my lecture on "American Nervousness, its Philosophy and Treatment." The reply is very simple. The facts in regard to the prevalence of hysteria and hysteroidal affections in the middle ages are not only admitted, but insisted on, by me. Indeed, I long ago called attention to the fact that affections of this kind were of a twofold character, *physical and psychical or mental*, and to the fact that the psychical or mental forms were far more common in the middle ages and among semi-barbarians, or, at least, among people but partially civilized, than in recent times. On the contrary, the physical forms of these diseases have arisen and developed with amazing rapidity during the last half century or more, in civilized countries. There are nervous diseases, and nervous diseases, and nervous diseases; to say that nervous diseases in general, as a whole, without regard to

their nature or origin, have either increased or diminished, would be unscientific.

The lecture which you criticized was devoted mainly to *physical* as distinguished from psychical forms of functional nervous diseases. This distinction is vital and fundamental, and has been again and again presented by me in discussing these theories. I quote the following paragraph from a paper of mine published in June, 1878, in the *Quarterly Journal of Inebriety*. The nervous diseases of this class described in this paragraph are *diminishing* with civilization and the increase of intelligence:—

"Hysteria appears under two quite distinct forms—the one psychical, the other physical. In the psychical or mental form the symptoms are the result solely of an unbalanced mind powerfully excited by some emotion. This form of hysteria occurs in persons who are vigorous and muscular; their bodies are strong but their brains are weak; they have more emotion than reason, and the few faculties they have being but slightly trained, they are easily 'thrown off the centre,' to use a nautical phrase, and when any great excitement appears they develop the symptoms of hysteria, with convulsions, contortions of muscles, anæsthesia, or numbness, and so forth. In modern times, and in this country, Irish servant girls illustrate very frequently this type of hysteria; in the middle ages large communities were thrown into a state of hysteria and of trance by mental excitement alone, and as functional nervous diseases were at that time comparatively unknown, it is just to assume that these epidemics of hysteria and hysterical disorders were largely if not entirely of a psychical nature—unbalanced and untrained minds acting on strong and vigorous bodies. In our time and country, among the higher circles of society, a very different type of hysteria appears; exhausted, neurasthenic bodies, under the influence of fatigue or worry of excitement, develop many of the same symptoms as are experienced by those afflicted with psychical hysteria."

The fallacy that destroys the reasoning of Hæser and other writers on this subject is, that they do not understand this distinction between psychical and physical diseases.

On this subject there is one other point of interest, namely, that structural organic diseases of the spinal cord are more common in Great Britain and Central Europe than in America, whereas functional nervous diseases, such as neurasthenia, sick headache, *physical* hysteria, and hay fever and inebriety, are more common in America than in any other part of the world.

The object of this lecture on American nervousness was not to bring out these distinctions, but to account for the nervousuess of the American people and to point out the methods for relieving it.

I may say also that the books of travel to which you refer agree in this, that such conditions as trance (under various names, as ectasy, somnambulism, catalepsy, possession, etc.), and what I call mental forms of hysteria, leading sometimes to actual insanity, have existed in all historic ages, and all over the world; this is a fact which is quite out of the range of discussion.

On the other hand, it is also a fact, based on the same evidence in part, that the functional diseases of a physical character to which I have referred were very rare indeed prior to the nineteenth century, and at the present time scarcely exist outside of the great centres of civilization. The facts of the relation of age to work, which you criticised some years ago, have not, as you say, been dropped, but will, in proper time, be published in permanent form, wherein your criticisms and those of others will receive most careful consideration. In closing I wish to express my appreciation of the intelligence, ability and courtesy, with which, on your part, our discussions have been conducted. Geo. M. Beard, M.D.

New York, Sept. 20th, 1879.

A Few Reasons in Favor of Physicians Dispensing Drugs.

Ed. Med. and Surg. Reporter:—

As to this matter, there is a reform needed throughout the profession, not only in the country but in the cities as well. To support this proposition there are reasons which cannot be put aside. I have recently noticed in some of our leading journals complaints as to the habit known as "counter prescribing." Now, it does not become the average medical man to utter a word against this procedure. The fault lies at his own door entirely. In our cities a party cannot consult a physician for the simplest ailment without incurring a druggist's charge in addition to the usual prescription fee. In the light of this fact it is not strange that many prefer to risk the apothecary's presumption, and seek advice and remedy under one consideration, rather than run the entire gauntlet.

We are not among the number who believe a physician has even a shadow of right on his side in saying "consultation free, and no charge except for medicines;" nor do we believe that this assertion is ever uttered outside the pale of quackery; certainly no *physician* could so far forget himself as to thus degrade his profession.

As in a previous article in the Reporter, of May 3d,* we definitely assert that much of the favor shown homœopathy is due to defects in regular practice.

It is a well-known fact that very many families have been induced to employ the man of the *infinitesimal potency* simply because at the end of a siege of sickness there is no druggist's bill, amounting well nigh to the charge made by the attendant. It seems to us that this point alone would warrant a physician in keeping and dispensing his own drugs. In this and other respects we allow ourselves to be brought into very unfair competition with homœopathy—a theory which will not bear scientific or trained inspection, and which must ever depend for its success upon devising means by which the masses may be intrigued. We do not mean for a moment that regular medicine should descend to meet these devices in any particular; but simply this, viz.: that so far as business competi-

* The word "plan," in the thirtieth line of that article, has been erroneously substituted for "flaw" in the manuscript.

tion on an honest plane is concerned, we should be more keenly alive to professional interest.

The next point we make is that many, and indeed most, physicians have very little idea as to whether the compounds they prescribe be nauseous or not; hence it has become proverbial that regular practice means nauseating and harsh medication. Indeed, very many, even among the more intelligent classes, hold the opinion that this is the main point at issue between ourselves and the followers of Hahnemann, and on this belief, preferring pleasant medicine, have been led to employ the latter. We must admit we are at fault in this particular, for there is not an agent of the Pharmacopœia, however nauseous and unpleasant in the unshielded form, that does not admit of being given, in the largest ordinary doses at that, in some menstruum or other capable of rendering it palatable. The literature upon this topic, however, is very scanty, and does not more than tally with the practice of the day. Then how become reasonably proficient in our knowledge of pleasant medication? Shall medical students be compelled to serve a certain period as practical pharmacists ere they deserve their diploma? This idea is not practical. Clearly, now, the most available way is that each medical man keep his own medicines and compound his own prescriptions. We do not mean to say this is the only way, but that it is *one* way, and that there is no objection to such a course whatever. I repeat, I do not advocate the handling of drugs as a means of speculation at all.

We are sure that many druggists who pass as respectable are in the constant habit of "substituting" in prescriptions sent them. I need scarcely mention the matter of frequent arrangements between druggists and practitioners by which the latter receive a percentage.

We would urge the above points to the consideration of the profession. J. W. Hickman, M.D.

Delta, Pa., 9, 17*th*, 1879.

Congenital Hydrocephalus.

Ed. Med. and Surg. Reporter:—

In the Medical and Surgical Reporter, Aug. 9th, 1879, Geo. Irvin, M.D., of Aledo, Mercer Co., Illinois, published a case of "Congenital Hydrocephalus," and asked if "any of the correspondents of the Medical and Surgical Reporter can suggest any better plan of delivering a hydrocephalic baby, than by decapitation?" As no one has complied with the Doctor's request, I beg to refer him to the *Transactions* of the Mississippi State Medical Association, for the year 1872, in which he will find a case reported by the undersigned, very similar to his own. In that case, a multipara, the body and limbs of the fœtus had been extruded for five or six hours, the head remaining immovable. "The patient was placed on her back, with her hips resting on the edge of the bed, legs supported by assistants, the child depending, and pressing upon the perineum. I passed Holmes' Perforator along the nucha of the child, carefully protecting the genital and urinary organs of the mother with two fingers of the left hand, until I reached the occiput; I then forced the instrument into the head, and expanded the blades; closing them again, I withdrew the point, made a half turn, re-introduced the instrument at the same opening and expanded the blades again, making a very neat crucial incision just posterior to the foramen magnum. On withdrawing the instrument there was a gush of liquid, which flowed into the *porte de chamber*, under cover, so freely that the question flashed through my mind, 'is it possible that I have wounded the bladder?' On pushing aside the cover, I was gratified to perceive that the fluid was neither urine nor blood. After the vessel was more than half filled with serum, the child's head was released without any force or effort. Thus the cause of detention proved to be intra-uterine hydrocephalus, which, if it could have been detected at the outset, would have required only a simple puncture with the trocar. But in such cases the anxiety and sense of responsibility are none the less, since the real cause of difficulty cannot be determined beforehand."

This case occurred in 1865. The patient recovered promptly and perfectly, and has borne several children since. Decapitation of the fœtus under such circumstances is certainly very unnecessary, and makes a difficult case out of a very simple one. J. M. Taylor, M.D.

Corinth, Miss.

Psoas Abscess or Hernia?

Ed. Med. and Surg. Reporter:—

"S. M. H.," in last week's issue of the Reporter, criticizes my article in the number for June 21st. But he seems to misapprehend my account of the case; and the words, "Probably if the doctors (plural) had used, instead of the 'blister,' a little judicious taxis, the 'abscess' would have disappeared, and with it all pain, heat and swelling," misrepresent my position in the case. I state, "I *found* the surface about the tumor discolored and sensitive, partly the effect of a fly blister which *had been* applied. . . Accepting the *history* as correct; and being misled by the condition consequent upon the blister" etc.; which shows that I had had no hand in applying the blister, and that the parts were in no condition for "judicious taxis" at this, my first, examination. And please notice that I say nothing about "heat and swelling."

After opening, "we directed our patient to be placed in a semi-recumbent posture, and warm poultices to be applied to the part. Suppuration soon commenced. . . I saw her again the next day. . . . Saw her again about three months after, and she was still quite comfortable and considered convalescent. *Pus continued to flow freely from the opening.*"

I gave no theory as to how the tumor disappeared nor the discharge, which followed, appeared; not deeming it necessary to an elucidation. Possibly the prick of the lancet caused the patient, who was extremely nervous, suddenly to lift the hips, when the sac, with its purulent contents, receded; and before the opening in the skin could close, air entered. Then raising the patient to a "semi-recumbent posture"

caused the pus in the opened sac to obey the law of gravitation and flow back to the opening in the groin, which was made by my "*frater medicus*" with an abscess lancet, and not, as "S. M. H." supposes, with a "bistoury."

When we consider the patient's "delicate appearance," the "general indications of a strumous diathesis, sensitiveness of the lumbar region," and an additional symptom, which I inadvertently omitted from my report, that of long-standing lameness, I think we have a right plain case of psoas abscess; and trust that "S. M. H." will acquit us of failing to appreciate so critical a situation. DELTA.

Montgomery Co., Md., Sept. 13th, 1879.

Medicinal Snuffs.

ED. MED. AND SURG. REPORTER:—

The following communication was sent to me, and will explain itself:—

DR. CARL SEILER: *Dear Sir*—On page 93 of your excellent treatise, you recommend, in the treatment of acute coryza, a "snuff composed of gum acacia, subnitrate of bismuth, bicarbonate of soda, and a little sulphate of morphia." Also, in the treatment of hay cold, on page 102, you likewise recommend "the frequent snuffing of a powder composed of gum acacia, quiniæ sulph., bismuthi subnitratis, and a little morphia sulph." I am at a loss to supply the proportions of the ingredients. If you would publish formulæ for these powders in the MEDICAL AND SURGICAL REPORTER, you would oblige

MANY PROFESSIONAL FRIENDS.

Phila., Sept., 17th, 1879.

In answer to it I would state that I refrained from giving the proportions of the formula referred to in my book, because they will have to be altered according to the peculiarities and idiosyncrasies of each particular case, but the following formula will be found to answer in most cases:—

℞.	Bismuth. subnit.,	ʒiij
	Pulv. gum acaciæ,	ʒij
	Quin. sulph.,	ʒj.
	Morph. sulph.,	gr.ij

M. et. pulv.

SIG.—Use as snuff, or by means of insufflator, 5–6 times a day.

The rationale of this is that the gum coming in contact with the watery secretions makes a paste, which, being thickened by the bismuth, protects the irritated mucous membrane from the influences of air and dust. The quinine is added with a view to prevent the growth of vegetable spores, and the morphia in order to lessen the sensibility.

In ordinary coryza, sodæ bicarb., ʒj, is substituted for the quinine, with a view to neutralize the acidity of the secretions. This remedy must, however, not be looked upon as a specific for hay fever or coryza, for although it gives relief in a great number of cases, yet I have found it to fail utterly in several. C. SEILER, M.D.

Phila., Sept., 25th, 1879.

NEWS AND MISCELLANY.

The Wines of Egg Harbor, N. J.

It has been found that the climate and soil of certain portions of New Jersey are admirably adapted to the cultivation of the grape, and that the wines made from the fruit are equal, in color, flavor, quality and keeping properties, to most of the old world vintages. On September 25th, several of the leading wine growers of Egg Harbor City asked, through the courtesy of the Camden and Atlantic Railroad Company, a number of prominent professional and business men to visit their vineyards and vaults. The excursion was a most interesting one. The varieties of wine are numerous, and we were especially pleased with a light white wine, called "Martha," grown by Mr. J. Furrer; a "White Concord," by Mr. A. Heil; the "Black Rose," by Mr. C. Saalmann; and the "Franklin," by Mr. J. Hincke, which last received a medal at the late Paris Exhibition. All these wines are the pure juice of the grape, without adulteration, and for medicinal and dietetic purposes are not surpassed by any in the market. Indeed, it would be difficult to find any so uniformly reliable. Of the speakers present, ex-Governor Pollock made an address, in which he said that it would be well for the cause of temperance if light wines, of the purity and virtue for which the vintages of Egg Harbor were noted throughout the country, were brought into more general use; and the Count d'Assi, of Italy, stated that they must be regarded as successful rivals of the famous vintages of his native land.

Progress of Metalloscopy.

The Paris Academy of Medicine decreed, in July, a prize of 2000 francs to Dr. Burq, the founder of "metalloscopy," as a token of its approbation, and to assist him in prosecuting further experiments. It is also noticeable that both in England and Germany several prominent writers who at first attributed the phenomena to expectant attention now state their belief that this is an insufficient explanation for all the observations recorded, though no doubt it will explain some of them. It seems probable some hitherto unappreciated force is also at work. A Paris correspondent of the *Lancet* writes: "In spite of the 'arbitrary skepticism' of the large majority of the profession, the most satisfactory results are daily obtained in the hospitals by the external application of metals. Symptoms of the most curious nature develop under their influence, and give rise to the most interesting discussions at the medical societies."

An Unlucky Victory.

A good story, and an authentic one, comes from Regensburg, in Bavaria. In that country physicians are not permitted to dispense medicines when there is an apothecary to do it for them. Three homœopathic physicians were practicing in the city, when an apothecary came

among them and notified them to send him their prescriptions. Two of them refused to obey, and were brought before the court and fined twenty marks. The case was carried to a higher court, and the medicines (pilules) were sent to the University of Erlangen for chemical analysis. The chemists reported that the pilules were made of pure sugar, and did not contain any medicine; whereupon the judge reversed the decision of the lower court, and declared there was no law against physicians distributing confectionery as freely as they chose.

Prevalence of Malaria.

We are informed that malarial disease is much less frequent and virulent in the Mississippi valley this fall than it was a year ago. It is certainly so generally in the valley of the Delaware, though in certain limited localities it is quite severe; for instance, in and near Fairmount Park there has been more fever among residents than for some years. People should not be in the Park, particularly in carriages, after the sun goes down.

American Gynæcological Society.

Our report of the annual meeting of this Society has been crowded out this week. It will appear in our next number.

Personal.

—Dr. Bulkley begins his third course of lectures on Diseases of the Skin, in the New York Hospital, October 8th.

Items.

—Nearly one-quarter of the births in Brussels are illegitimate.

—At the Russian Hygienic Society, M. Malarewsky, speaking of the progress which myopia is making among studious persons, has proposed that printing should in future be executed by means of white letters on a black ground. This system has been tried by experiments made simultaneously on fifty persons, and the results obtained have been sufficiently conclusive for physicians to encourage the proposed reform, which would constitute a revolution in the art of printing.

OBITUARY NOTICES.

—Died, at Castleton, N. Y., on the 9th inst., of inflammatory rheumatism and paralysis combined, Dr. Myron Edson, of Castleton, aged 33 years.

Dr. Edson was taken sick in camp at Lake Bomoseen. He had a large and lucrative practice in his profession; was an amiable, good citizen, and a good husband.

—Dr. Cyrus B. Smith, of Granby, Mass., was killed by lightning Sept. 7th. He was in bed at the time the house was struck, and his death was instantaneous. Dr. Smith was born April 24th, 1839. He was surgeon in the 37th Massachusetts regiment, and made an honorable war record. In 1871 he represented the 5th Hampshire district in the Legislature, where his services were appreciated. In town affairs he took an active part. As a family physician he was highly esteemed, and will be greatly missed.

QUERIES AND REPLIES.

Dr. H. M. H., of Ill., asks:—"What is the most efficient means of treatment for chronic nasal catarrh? Is it generally acknowledged by the profession to be curable? Cannot some of the readers of the 'Indispensable Reporter' give me some light on its treatment? I am sure it would please a great many in this latitude."

Dr. H. W., of N. Y.—An editor is not responsible for statements made by correspondents; still less for those made by advertisers. It is sufficient to say that this journal does not and will not admit any advertisement which the editor believes to be deliberately deceptive or fraudulent in character; beyond this his editorial responsibility does not extend.

Dr. L. L. and others call attention to the omission of an important sentence on page 251, in the report of Dr. Harkin's treatment of the hemorrhagic diathesis. The salt he refers to is *chlorate of potash.*

Dr. S. K. L., of Mo.—Bitartrate of potash has been used to check bleeding in both hematuria and internal hemorrhoids. See Stone's *Therapeutics*, p. 147.

MARRIAGES.

CHASE—PALMER.—In the Methodist Church, on Walnut Hills, Cincinnati, Ohio, Dr. Harry R. Chase, of New York, and Miss Marian Palmer, of the Chickering Institute. The ceremony was performed by Elder Hypes, in accordance with the Episcopal service, by request.

PHELPS—DRAPER.—In Brattleboro, Vt., August 21st, by Rev. George E. Martin, Dr. O. W. Phelps and Mary Draper.

SWISHER—THOMSON.—In Healdsburg, Cal., July 31st, by Rev. S. H. Thomson, LL.D., Dr. J. R. Swisher and S. May Thomson, daughter of the officiating clergyman.

DEATHS.

BERNACKI.—On Saturday, August 16th, at the residence of her sister, Florida, Orange county, New York, after a lingering illness, Sarah E., wife of Dr. C. W. Bernacki.

BOYD.—In Newport, Vt., Aug. 20th, Mrs. Rebecca, wife of the late Dr. Boyd, aged 79 years and 9 months.

COLLINS-KLEIN.—At Opiez, Canton Berne, Switzerland, on Sunday, August 31st, Mrs. Helen E. Collins, wife of Dr. Theo. H. Klein, and niece of the late George C. Collins, Esq.

FINLEY.—In this city, on the 8th ult., Clement A. Finley, Surgeon General U. S. Army, retired.

HAIGHT.—At Stamford, Conn., on Friday evening, Sept. 12th, Nathaniel D. Haight, M.D., aged 76 years.

HUMBERT.—In New York, on September 17th, Dr. Wm. H. Humbert.

PEACE.—At Annasdale, Delaware County, Pa., after a brief illness, Edward Peace, M.D., in the 69th year of his age.

WHITE.—In Cincinnati, Ohio, September 7th, of chronic pneumonia, Dr. John B. White, dentist, in the 34th year of his age.

WILSON.—At Babylon, Long Island, September 18th, Laura T., wife of Dr. Geo. A. Wilson.

WOLCOTT.—At Delanco, N. J., on the 26th ult., Charles Rhaesa Wolcott, M.D.

HORSFORD'S
Acid Phosphate,

(LIQUID.)

For Dyspepsia, Mental and Physical Exhaustion, Nervousness, Diminished Vitality, Urinary Difficulties, etc.

Prepared according to the directions of E. N. Horsford, late Professor in Harvard University.

The value of this preparation of Acid Phosphate was long ago theoretically demonstrated, and has since been firmly established by experience obtained from its continued use in a great variety of cases, in every part of the country. It affords nourishment to the cerebral and nervous systems, and restores to their normal action deranged secretory organs, and gives vigor and renewed strength to the human system when weakened by overwork.

There seems to be no difference of opinion in high medical authority, of the value of phosphoric acid, and no preparation has ever been offered to the public which seems to so happily meet the general want as this.

It is not nauseous, but agreeable to the taste.
No danger can attend its use.
Its action will harmonize with such stimulants as are necessary to take.
It makes a delicious drink with water and sugar only.

Prices reasonable. Pamphlet giving further particulars mailed free on application to manufacturers.

Physicians desiring to test it will be furnished a bottle free of expense, except express charges.

MANUFACTURED BY THE

RUMFORD CHEMICAL WORKS,

1155-1206 PROVIDENCE, R. I.

DE DUDLEY'S EMULSION DE
OF PURE
NORWEGIAN COD LIVER OIL
PANCREATINE
AND
DE LACTO-PHOSPHATE OF LIME DE

FORMULA.—Each fl. oz. contains six grs. of Pancreatine, sixteen grs. of Lacto-Phosphate of Lime, twenty-five per cent. of Glycerine, and **fifty** per cent. of Norwegian Cod-liver Oil.

THE ONLY PANCREATIC EMULSION MADE IN THE UNITED STATES.

This preparation is respectfully submitted to physicians as being **always** reliable. Although well aware that Cod-liver Oil Emulsions have fallen into deserved disrepute, yet we are confident this will stand any test or trial it may be subjected to. It contains no GUM ARABIC, TRAGACANTH, ALBUMEN, SACCHARINE OR ALKALINE MATTER; therefore, it will not SAPONIFY, FERMENT nor RANCIDIFY. The addition of **Pancreatine** insures rapid and complete assimilation, enabling patients with very weak stomachs to easily retain and digest it.

Guaranteed to keep in any climate. Physicians supplied with samples (express paid) on application.

DUDLEY & CO., Pharmaceutical Chemists,

Laboratory, 397 and 399 Pearl Street. **423 Fulton Street, Brooklyn, N. Y.**

MESSRS. DUDLEY & CO.: *Dear Sirs*—Though your EMULSION has not been before the profession a long time still I have used it quite extensively in my practice, and can truly say I think it one of the most elegant preparations of Cod-liver Oil I have ever prescribed. I find it can be readily taken and borne by the most delicate stomach, and the PANCREATINE and PHOSPHATES make its administration desirable in a large number of cases other than phthisical. In fact, there are few cases of mal-assimilation and general debility in which its administration will not do good; and it gives me pleasure to recommend it to my professional brethren.

1179- HOMER L. BARTLETT, M.D., Brooklyn, N. Y., Consulting Surgeon Kings County Hospital.

NEW REMEDIES.

FLUID EXTRACTS.

Coto Bark.—From BOLIVIA. Almost a specific in acute and chronic diarrhœa, cholera, cholera morbus, etc.

Cascara Sagrada.—(**Rhamnus Purshiana.**) From the PACIFIC SLOPE. A certain remedy for habitual constipation; and very useful in all cases where a laxative or cathartic is indicated. Beware of the fluid extracts of spurious varieties of this bark.

Folia Carobæ.—From BRAZIL. A powerful alterative, which exerts a marked curative action in syphilis, scrofula and kindred disorders.

Rhus Aromatica.—A remedy in diabetes, and other diseases of the genito-urinary organs.

Damiana.—(**Turnera Aphrodisiaca.**) From MEXICO. The best known aphrodisiac. Of great value in impotence, spermatorrhœa, and loss of sexual appetite.

Boldo.—(**Peumus Boldo.**) From CHILI. The new tonic. Very useful in dyspepsia, hepatic torpor, yellow fever, etc.

Berberis Aquifolium.—From CALIFORNIA. Has marked alterative and tonic powers, and has been used with extraordinary success in salt rheum, psoriasis, eczema, scrofula and syphilis.

Black Haw.—(**Viburnum Prunifolium.**) From the UNITED STATES. Employed to prevent abortion and miscarriage.

Grindelia Robusta.—From CALIFORNIA. A valuable curative agent in asthma and diseases of the air passages.

Grindelia Squarrosa.—From CALIFORNIA. Anti-malarial. Used in enlarged spleen and other malarial diseases.

Cereus Bonplandii.—(**Cereus Grandiflorus and Cereus McDonaldii.**) From MEXICO. Heart sedatives. Very useful in controlling functional and organic disturbances of the heart.

Kaki.—(**Diospyros Kaki.**) From JAPAN. Peculiar action on the mucous surfaces. Useful in mucous dyspepsia, typhoid fever, etc.

Cercis Canadensis.—Indigenous. A positive remedy in chronic diarrhœa, dysentery, etc.

Jaborandi (diaphoretic). **Guarana** (sick headache). **Fucus Vesiculosus** (anti-fat).
Bearsfoot (enlarged spleen). **Coca** (nervous stimulant). **Kava Kava** (Gonorrhœa).
Eucalyptus Globulus (antiseptic and anti-malarial). **Yerba Santa** (coughs).
Yerba Reuma (catarrh). **Wood Betony** (dyspepsia). **Ustilago Maidis** (oxytocic).
Penthorum Sedoides (catarrh). **Soap Tree Bark** (tooth wash).

CRUDE DRUGS.

Goa Powder (ringworm and diseases of the skin). **Gurjun Balsam** (a substitute for Copaiba).
Alstonia Constricta (a substitute for Calisaya).

SUGAR-COATED GRANULES.

Calcium Sulphide 1-10 gr. (for the cure of boils and carbuncles).

Our limited space prevents our describing in detail the history and application of each remedy, but to those interested in NEW REMEDIES, we will say, that we can furnish interesting information relative to the above new drugs.

PARKE, DAVIS & CO.,

DETROIT, - MICHIGAN.

Our New Remedies can be procured of the Drug Trade throughout the United States. By specifying **"P., D. & Co.'s"** in all cases, you will ensure reliable preparations of the **true drugs.**

WITH

EXTRACT of MALT,

A combination we have lately added to our list, in response to a demand from physicians of this city, who have used our **Pure Cod Liver Oil** and other preparations. The praise accorded by all who have used it induces us to seek a wider market by calling general attention to it.

A Trial is Respectfully Solicited.

Our facilities for the manufacture of

THE EXTRACT OF MALT

are unsurpassed, and perfect reliance may be placed on the article bearing our label.

Above are in full pint bottles, and with our other specialties:—

Baker's Pure Cod Liver Oil,
" *C. L. O., with Phosphate of Lime,*
" " " " *and Wild Cherry,*
" " " *Hypophosphites of Lime and Soda,*
" " *and Malt with Syr. Iod. Iron,*

Are supplied by the drug trade generally.

An astringent and balsam combined, in most convenient form for application. Rapidly becoming popular with physicians. Descriptive circular and endorsements mailed on request. Boxes of 14 suppositories to physicians, 75 cts., by mail.

THE TREATMENT OF SPINAL DISEASES.

BY E. H. COOVER, M.D.,
Of Harrisburg, Pa.

In the Medical and Surgical Reporter of April 13th, 1878, I offered a paper, entitled, "Suggestions in the Treatment of Spinal Diseases and Curvature," in which I claimed the use of a closely fitting jacket or corset, made from several layers of unbleached muslin, stiffened by a solution of the silicate of soda, as being an appliance which, in my experience, offered a greater measure of success than any other hitherto adopted. I instanced a number of cases in which this treatment rewarded me with the most gratifying results, and which satisfied me beyond question that if adopted by the profession it would insure a more uniform success in the treatment of this class of diseases. Since the appearance of that article I have made a number of improvements in the mechanical construction of the jacket, and as my professional duties will not afford me opportunities to reply in detail to the many letters of inquiry with which my professional brethren have favored me, I have concluded to place the results of my recent experiments and experiences before them through this medium. I do not want to be understood as detracting from the credit hitherto accorded eminent practitioners who have preceded me in this direction, nor do I wish to claim the method of treatment as original with myself. My claim is solely upon the mechanical construction of the jacket, and I feel certain that a fair comparison with others will show that the process employed by me in its manufacture admits more readily of subsequent alterations, thus enabling the surgeon to adapt it perfectly to the particular case under treatment.

The process as employed is as follows: From unbleached muslin are cut four pieces, shaped like the fronts and back of a coat or bodice, and long enough to reach below the pubes and hip joint. The patient being clothed in a tight-fitting, seamless garment, and seated upon a stool something higher than an ordinary chair, the back pieces are laid on and wetted with the solution of silicate of soda. The top and bottom edges are laid carefully together and the intervening edges being cut purposely will show an elliptical opening; this is done for the reason that when the pieces are pressed to place, the edges will meet without overlapping, thus making the jacket conform to the natural curve of the back. Until recently it was not considered necessary to get that curve until the jacket had been formed, but now I find it can be done by this method upon the patient, thus securing a better fit, while it really occupies no more time in adjusting.

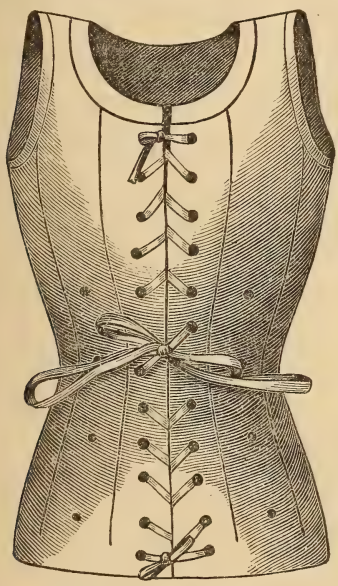
The fronts are then put on in the same manner, after which a silicated soda bandage, from three to four inches wide, is passed around the body, from a point immediately under the axilla to the hip joint; this fixes the body pieces and secures a firmer structure upon which to build the more substantial part of the apparatus, besides obliging the jacket to conform strictly to the body of the individual. Braces of tin—slit at short intervals along their entire length and nearly an inch from the edges toward the centre, like a many-tailed bandage, in order to make them more pliable in adjusting—three inches wide at

top and five or six at bottom, reaching from near the axilla to a point beyond the crest of the ilii, are next placed in position and covered by pieces of muslin wet with the silicated solution. Other braces of tin, an inch wide, and extending from the junction of the fourth rib with the os sternum to a point near the symphisis pubis, are placed, leaving a space of about an inch or more on each side of the median line, where the jacket will be cut for the purpose of eyeleting. Still another brace of tin, one and a half inch wide, is placed along the spine, shaping it also to meet the contour of the parts. The patient is now extended with Dr. Sayre's apparatus, and a bandage similar in dimensions to the one alluded to prior to applying the braces, is carried around the jacket, over the braces, being saturated with the solution as it advances, applied by a brush in the hands of an assistant. Care should be taken not to "trice the individual up so high that the support afforded by the heel is lost, as, in my opinion, without this precaution the spinal column is too much straightened by the weight of the lower extremities, and the natural curvature thereby lessened. This latter bandage secures the tin braces firmly in position, and retains them there without further support. A second or outer bodice, made exactly like the first, is now framed and applied, using the silicate of soda freely in order to secure its uniform adhesion to all the inequalities which the surface of the jacket now presents. This completes the jacket for the present, and the patient being lowered, is carefully laid upon a firm bed (care being taken in the transit to disturb the set of the jacket as little as possible) and allowed to remain at perfect rest for a period of four or five hours, at the end of which time the silicated material will have become sufficiently firm to admit of further manipulation. The jacket is removed from the body by making an incision along the centre in front and carefully slipping it off. Before cutting, however, it should be carefully trimmed, or marked where trimming is necessary, under the arms and at the bottom. It may be cut off at the top, both back and front, as low as the patient may desire, provided always that it is not desired so low as, in the judgment of the physician, will interfere with the proper support of the affected structures. At the bottom it should be made to extend at least two inches below the crest of the ilii, and cut off in the direction of the symphisis pubes, so that the lower part of the jacket, when the patient is seated, will not rest heavily on the thighs, thus pushing it up and out of place, rendering the patient uncomfortable and defeating the object intended, a perfect support.

If after cutting the jacket prior to its removal the edges should overlap when brought together, showing too much material, they should be trimmed off so as not to meet, by one-half to one inch. This is very necessary, as changes frequently take place in the fullness of the body of the patient, and if the jacket does not press firmly and evenly upon the whole surface, a condition impossible at all times if the edges meet, the support necessary to the comfort of the patient is lost. Always remember, in trimming off edges, to remove equally between the two sides, where the centre of the jacket is the part manipulated, otherwise it will give the apparatus a one-sided appearance. For convenience in the further mechanical construction, I remove the jacket to my office, where I can have more conveniences at command. It is yet in a semi-plastic condition, the heat of the body not being sufficient to render it as hard as it must be to answer the purpose for which it is intended. I place it upon a table and remove the inner bodice, smooth out all the folds or wrinkles, taking great care not to destroy the shape. This done, it is removed to a hot stove, and placed over or beside it, not near enough to scorch, supporting it artificially, if necessary, to preserve the shape. When the material is sufficiently hardened, I place it over a rounding block, and with a round-faced hammer pound down all the roughnesses and projections left upon the inner surface. I then line the inner side with pieces of muslin, using as an adherent the silicated solution, and bind the arm spaces and all the trimmed edges with pieces of muslin cut bias, not sewed on, but attached by the use of the soda. This is done to prevent the separation of the different cut edges, and render the jacket more durable. The front edges are now eyeleted and supplied with a suitable lace or draw string. Several rows of holes, about the size of a No. 15 or 16 catheter, should be made in the jacket, with a steel punch, over a hard block of wood. This will allow the escape of the natural exudations of the body, and will afford all necessary ventilation. All openings should be made from the inner surface outward, in order to prevent the formation of prominences on the inside of the jacket. The instrument is now ready to be placed upon the patient. In order to ascertain whether the curve in the jacket, particularly that of the region commonly termed the "hollow of the back," is correct, measurements should be taken of the patient and compared with those of the jacket.

This is most conveniently done with a common yardstick, by placing it upon the protuberance and measuring the arc described between with a common rule. The anterior curve, or that denominated the hollow of the back, is ordinarily from an inch and a quarter to an inch and a half, and the jacket should be made to conform to it, in order to give that support to all the anatomical structures which is necessary to a successful treatment. If any alteration in the jacket is necessary to its proper conformity, it may be accomplished by slitting the jacket at that part and removing an elliptical piece; the opening thus made is drawn together by punching holes in either edge, and drawing together by means of a lacer of linen tape.

I have now carefully and minutely described



the mechanical construction of my jacket, and feel assured that if my professional brethren will follow my process strictly success will follow their efforts, not only in the construction of the instrument, but in affording relief to those of their unfortunate patients to whose infirmities support is rest; and rest is the natural therapeutic agent for the relief of pain.

If the patient is a female, it is my custom to support the breasts, before applying the jacket, with strips of adhesive plaster, keeping them well up to their natural position; I then further protect them from undue pressure by breast shields. When about to adjust the jacket upon the patient finally, he or she should be extended in Dr. Sayre's apparatus, which is well designed for that purpose, taking care not to go beyond the former suspension, or, in other words, depriving the patient of the support afforded by the heels. The jacket is then put around the body and set to its place. It is now ready for lacing. Begin with the long lacer, about the third eylet hole from above down, and go down as far as the umbilical region, where, drawing it through and making a loop long enough to tie on either side, proceed lacing until the lower edge is reached, where it is fastened. The object in leaving the tie loop in the umbilical region is to draw it tightly together at that point, thus making extension and counter extension at the same time, the bony structures of the scapula and iliac region serving as fulcrum, as it were, and the space between the weight. Then take a short lacer or linen tape and lace it through the upper holes, drawing it as tight as the patient will allow, and tie it. The object of this short and separate lacer is to afford the patient, if a female, an opportunity to relieve the mammæ from undue pressure. No dinner pad is necessary with this jacket, as the patient may find relief after a hearty meal by simply loosing the lacer or tie loop for an hour or two, when it is again tightened. In females who suffer from uterine displacements this jacket affords a perfect support, and in no single instance have I learned of any ill effect resulting from the use of it, on young or old.

It is light, and quite inexpensive; the quantity of the solution of silicate of soda used is about three pounds, to make a jacket of the largest size, but as it has to be applied hurriedly, at least one-half is wasted, not leaving more than a pound and a half in the jacket, when dried, to add to its weight—specific gravity 1.2755 in summer and a little higher in winter—costing only 35 cents, and muslin at eight cents a yard will not add greatly to the cost of the whole. The silicated solution does not set as quick as the plaster-of-Paris, nor is it liable to crack or crumble, and it is more durable. The lacing admits of its removal at any time, for the purpose of cleansing the body, and after the first adjustment no extension of the spinal column is required by the apparatus above named; the patient takes it off and puts it on without assistance. The weight of the jacket is fifteen ounces to three pounds, according to size. The time required to mould it on the body is from thirty to forty minutes.

[Dr. Coover adds the notes of a number of cases, which we regret the crowded condition of our columns prevents us from inserting. They exemplify the principles which he has above detailed.—Ed. Reporter.]

BELLADONNA IN DISEASES OF CHILDREN.

BY CHARLES H. HALL, M.D.,
Of Macon, Ga.

A German writer says the subjects to whose diseases belladonna corresponds most exactly, are those whose cerebral functions are most liable to become irritated, or whose brains, and consequently heads, have the greatest development, *i.e.*, children. It is a well known fact that children bear and require proportionately larger doses than adults. In all the active hyperæmia of the brain of children it is of conspicuous benefit. This hyperæmia is a very common accompaniment of the febrile diseases of childhood, and frequently blinds us as to the true diagnosis of their affections. We must wipe away this hyperæmia, or convulsions are apt to supervene, which will still more complicate the case and increase the danger to our little patients. Belladonna and the bromides will control this congestion, and however threatening the condition may seem, we may rationally offer hope to parents or friends. Where there is more than hyperæmia, and inflammation is present, or a meningitis, belladonna is no longer the remedy; the thermometer will aid this diagnosis. If in any of the diseases of children I find fever, with a red face, a disposition to sleepiness, and the eye reddish, indicating a possible brain complication, I constantly prescribe belladonna, and am scarcely ever disappointed in its effects. It does not seem to benefit anæmic and bloodless looking children so favorably as those who are florid, and it is especially beneficial to those who are plethoric and corpulent. In the early stages of infantile bronchitis, where there is considerable fever, and the wheezing just commencing, this drug will frequently seem to cut short the attack. If it is not so successful it will greatly modify the fever and relieve the congested mucous membrane—sore throat, inflammation of fauces, "all those parts behind the mouth which become visible when the jaws are widely opened and the tongue depressed." This is one of the commonest troubles which beset us in our daily rounds, and to our patients one of the most unpleasant. I was taught to give nauseants, purge, use counter-irritants, cauterize, give anodynes. If relieving "quickly, pleasantly and safely" is our desire, we have in belladonna a remedy that will seldom disappoint us; especially is it indicated where the membrane has a red, velvety look. If we have a temperature higher than one hundred and one, aconite combined with it makes the recipe all that the majority of these cases need. Two or three days will accomplish more than six to eight under the old plan of treatment. Its remedial power is not confined to the throat alone; any inflammation of the buccal mucous membrane is benefited by it. In stomatitis it is one of the best and most speedily successful remedies. I have frequently and fully tested this, giving and withholding in parallel cases. Last summer (1879) there seemed to be an epidemic tendency to stomatitis and I (as often before) gave it frequent and full trial. It is specially useful where you see your case early and can give it in the first stages of the disease.

In fact, belladonna appears to have curative powers in all inflammations of mucous membranes. From its now well-known, and I believe universally admitted, power in controlling excessive perspiration, we can readily believe in its pleasantly influencing such inflammations. Speaking of its controlling perspiration reminds me of its peculiar efficacy in lessening the temperature in the fevers of children which are characterized by sweating, although the temperature is very high. I have to-day (June 28th, 1879) two patients, one six, the other eight years; they each have had fever for ten days, temperature running 101 to 102 morning; evening 104 to 105; yet their skin was never dry, generally bathed in perspiration. Quinine, mineral acids, spirits of mindereri, baths, etc., apparently had no good effect; temperature still high. Two days' use of tincture belladonna in the one, and three days in the other, gave me a morning temperature of 100, and an evening 101 to 102. I have for years considered high temperature and perspiration an indication for belladonna. This is a "wrinkle," as Fothergill would express it, that remembering has aided me in relieving such fevers.

We are all acquainted with Mr. Liston's use of this drug in erysipelas. I use it in all the eruptive fevers of children. The exanthemata all possess the common property of febrile symptoms and cutaneous eruption. I avail myself of the benign influence of the drug, without reference to what the eruption may be, believing that it prevents the localization of throat trouble in scarlet fever, mitigates the bronchial troubles of measles, and is the "physiological antagonist" of the diseased action in all these diseases. A constant physiological action of belladonna is "a peculiar bright red flush," not only appearing on the face and neck, but over the whole body. That common trouble of children, incontinence of urine, is more constantly cured by this agent than any other; this use of the drug is, I believe, recognized by therapeutists.

It is one of our best remedies in an irritable state of the bladder, when it has been caused by cold. Indeed, all the vesical troubles of childhood are greatly benefited by it. In retention, I not only give it internally, but use the ointment over the perineum and hypogastrium. The external application of belladonna gives great relief in the myalgias and other painful affections of early life.

In the commencement of whooping-cough, before the convulsive stage is developed, I rely upon it, almost to the exclusion of other drugs, and have found very few cases that it does not modify. Other remedies are better suited to the subsequent stages of the disease.

The dentition of children is very constantly attended with diarrhœa, vomiting, etc. Although belladonna will of itself not relieve these morbid conditions, yet it will greatly aid our mercury, alkalies and astringents, by the influence it exerts over the nervous phenomena which is invariably associated with this condition. Calm this nervous irritation and we will much and more speedily relieve than if we neglected this important factor. It does more than influence the nervous element in this disease; where the actions are large and watery it positively lessens the size of the actions, although not their frequency. Recollecting its influence on the mouth and throat, the dryness it always produces, we can readily understand its beneficial effect, lessening the secretions of the intestinal mucous membrane. There is a general disposition in the profession to mistrust the inherent tendency to recover in almost all diseases. This disposition causes them actively to interfere, to treat disease as an enemy, and to endeavor to rout it by spoliative and aggressive measures. This is, to me, not philosophical nor in accordance with nature's laws, as we see them in daily operation; we should gently aid this inherent disposition toward recovery; proportion our help to the necessities of the case. I am convinced that the beneficial effect of belladonna in the class of diseases which I have mentioned is frequently lost by the dose being too large. I believe that the manner of its employment has everything to do with its efficacy. The true medicinal dose is far below the physiological dose. It is true, that the physiological dose frequently aggravates the disease, whereas the medicinal dose will favorably influence and hasten the recovery. My rule is to diminish the quantity I am giving whenever I see any approach to its physiological effects. It is true, that children bear belladonna better than adults, yet I have seen many very easily brought under the physiological effects. Therefore, as a rule, I give small doses, but whatever dose I select I give often, every fifteen or thirty minutes, until some amelioration or change occurs, and then make the interval greater. In this way I speedily arrive at my conclusions in regard to both the dose to be continued and the drug's suitableness to the case in hand. Given in this way its delightful therapeutic effects are obtained in the diseases I have enumerated. A well made tincture of the leaves is to be preferred to all other preparations.

Hospital Reports.

JEFFERSON MEDICAL COLLEGE HOSPITAL.

SURGICAL CLINIC OF S. W. GROSS, M.D.

Reported by Dr. F. Woodbury.

Spindle-celled Sarcoma over the Olecranon Process.

Mrs. A., a widow, 61 years of age, came to the out-patients' department on the 20th of last August, on account of a tumor, which was seated over the posterior face of the right elbow joint. She then stated that she first observed a small swelling, two years previously, at the spot indicated, which was painless, and of moderately soft consistence. Its further growth was slow until two months ago, or about June 20th, when it began to increase rapidly and be the seat of a gnawing pain, which was worse at night, and frequently materially interfered with her rest. On the 6th of August it began to ulcerate at its summit, and the suffering was aggravated; and a week subsequently the ulcer was the seat of a pretty free hemorrhage. From the model, which was made at the time by Dr. Nardyz, you will observe that the conoidal tumor surmounted the region of the olecranon process and the tendon of the triceps muscle. The skin was of a bluish-red tint, pervaded by enlarged capillary vessels, and attenuated. At its base the neoplasm measured eleven inches in circumference, and was three inches high, and its apex was ulcerated to the extent of an inch in diameter. In outline it was lobulated; its consistence was soft and elastic, and apparently fluctuating over the more prominent bosses; and its temperature was three degrees higher than that of the opposite arm. The veins in the immediate vicinity of the growth were more prominent than in the natural condition, but the lymphatic glands along the course of the vessels and in the axilla were not enlarged.

During the three weeks and a half which have elapsed since the patient first came under observation, the tumor has undergone very marked changes. Thus, its circumference has increased two inches and its height three inches, while the ulcer measures three inches and a half in diameter. The bosses have also increased in size, and the largest one fluctuates distinctly, and is approaching ulceration. During the past week the pain has greatly decreased under the local ap-

plication of a strong solution of acetate of lead and opium, but the ulcer was the seat of another hemorrhage three days ago, which my resident, Dr. Kneedler, controlled by compressing the brachial artery.

From the history of the case, the peculiar appearances of the morbid growth, its situation and mobility, I have no hesitation in pronouncing the tumor to be a sarcoma developed in the subcutaneous connective tissue over the olecranon process. In former days, or when our knowledge of the minute structure of neoplasms was imperfect, such a growth would have been pronounced a fungus hematodes, or hematoid carcinoma; but the idea of carcinoma may at once be dismissed, as comparatively recent researches show that the connective tissues are never the primary starting points of that class of tumors. In making a differential diagnosis as to the variety of tumor present in this case, I may say that the only primary neoplasms of the subcutaneous connective tissue of the upper extremity, exclusive of the hand, are lipoma, sarcoma, fibroma and myxoma. Of these, the fatty tumor is the most common; sarcoma comes next in point of frequency, but it occurs in the proportion of only one to five of the former growth; fibrous tumors are rare; and myxoma is still more uncommon. A fatty tumor in this situation should be pendulous or pedunculated. Its growth would be slow and painless; its consistence would be doughy; the skin would not be altered in texture or color, nor would there be ulceration. A myxoma has the same lobulated outline as a lipoma, but its consistence is soft and fluctuating, and it grows more rapidly. Its differentiation from sarcoma would depend upon the absence of ulceration, hemorrhage, and alterations in the skin. I have never heard of a mucous tumor being seated in this region, and its occurrence is, moreover, so rare, that it may be excluded. Fibrous tumors of the connective tissue never attain so large a bulk as the growth before you. They increase slowly and their consistence is firm.

Sarcoma may appear at any time of life, from infancy to old age, but it is most common between the twentieth and fortieth years. Two weeks ago I saw a child only twenty-four months old, with a myeloid sarcoma of the upper extremity of the ulna, which began to develop at three months of age. This afternoon I will examine the body of a mulatto boy, four years and three months old, who died of extensive sarcomatous disease, the primary tumor having originated from the medullary canal of the left humerus, from which, as a focus of general infection, secondary tumors have appeared on the left half of the head, in the left femur, the right humerus, and in the abdominal lymphatic glands. Only three weeks ago I removed, in this building, from a female, forty-one years of age, a cystoid round-celled sarcoma of the mamma. There is now in one of the private rooms a gentleman, upward of fifty, whose thigh will be amputated at the hip joint on next Saturday, on account of a recurrent hemorrhagic sarcoma of the soft parts of the thigh. The next case that I shall bring before you is one of giant-celled sarcoma of the radius of a colored woman, fifty-nine years of age; and I have in the museum a specimen of small round-celled sarcoma of the bladder, which was taken by Dr. Hearn, a few days ago, after death, from one of our out-patients, fifty-nine years of age. Hence, you will observe that sarcoma is met with at all periods of life, and is just now very common among those who present themselves here for relief.

Excision of the morbid mass is out of the question in this case, as it would be impossible to remove all of the infiltrated tissues about its base. Hence I shall amputate the arm at the junction of its middle with its lower third, making skin flaps by cutting from without inward, with a circular incision of the muscles, and reflecting the periosteum for one inch before dividing the bone.*

Having made a section of the tumor and the underlying bones, which was attended with the escape of straw-colored fluid, Dr. Gross described it in the following terms:—"The tissue of the tumor is for the most part succulent, glistening, striated, and yellowish-white, with here and there gelatinous areas and a few cysts, the largest of which equals a hazlenut in size. The older portion, or that which lies nearest to the olecranon process, is deeply blood-stained. The triceps tendon is involved in the disease, but the ulna itself is free, the tumor, which developed in the subcutaneous connective tissue, being merely attached to the outer layer of its investing periosteum. From the peculiar appearances of its structure, I do not hesitate to pronounce it a spindle-celled sarcoma undergoing myxomatous and telangiectatic degenerations."†

Giant-celled Sarcoma of the Lower Third of the Radius.

The next case that I bring before you is that of a married colored woman, 59 years of age, who has a large spherical tumor of the lower third of the forearm, without, however, involvement of the wrist joint. She states that she first observed, about twelve months ago, an immovable growth, as large as a hickory nut, two inches above the wrist, and on the radial side of the limb, from which it continuously extended in every direction, until, as you now perceive, it surrounds the entire lower third of the forearm, and measures three inches more in circumference than the same limb at a corresponding point. In outline it is spherical and bosselated, the bosses having appeared during the past three months. It is the seat of preternatural heat; but the skin, veins, and lymphatic glands are entirely normal. On making a careful examination I find that while the tumor has for the most part a firm feel, the bosses alone being soft, at the mid-point of

* Esmarch's apparatus having been applied, the limb was removed in the manner stated by the operator. Two arteries only required ligation, and oozing from the paralyzed vessels was controlled by douching the flaps with hot water. The parts were then brought together by interrupted sutures and adhesive strips; a tent inserted into the most dependent angle of the wound, for drainage; and the stump was covered with lint imbued with sweet oil, and confined by a roller.—*Reporter.*

† The correctness of Dr. Gross' diagnosis was verified by minute examination of stained sections, made by Dr. W. G. MacConnell.—*Reporter.*

its palmar aspect there is a sensation of a partial bony shell, and that the outline of the ulna can be traced upon its inner side. Hence I conclude that we have to deal with a sarcoma growing from the medullary canal of the radius, and limited by an osseo-periosteal capsule.

Sarcoma of the bones, improperly termed osteosarcoma, may consist of a structure made up of spindle, round, or giant cells, and, in accordance with the prevalence of one or the other of these elements, is termed spindle-celled, round-celled, or giant-celled sarcoma, the last variety being synonymous with myeloid tumor. In many specimens, however, no particular form of cell predominates, in which event we speak of a mixed sarcoma. Up to a comparatively recent period these tumors of the bones were called cancers, but we are now pretty well satisfied that there is no such a disease as a primary carcinoma of the bones. Despite this fact, however, sarcoma is par excellence the malignant tumor of the osseous system, although it is not so destructive to life as carcinoma of the glands, and it is malignant because it is an atypical connective tissue neoplasm, just as carcinoma is an atypical epithelial neoplasm.

Tumors of the long bones are, in the order of their frequency, sarcoma, chondroma, osteoma, osteoid chondroma, fibroma, and myxoma, the first being more common than all the others combined. They may be of central or peripheral origin, or develop from the medullary cavity or from the soft layer of the periosteum, the tumors of central origin being the most frequent. The sarcomata are all malignant, that is to say, they infect the adjacent tissues and occasion secondary deposits in the internal organs, but without, as a rule, contaminating the intervening lymphatic glands. The degree of malignity varies in accordance with the seat and structure of the growth, the periosteal forms and the small spindle- and round-celled tumors being the most destructive to life. To be more accurate, they may be classed in the order of their malignity, as follows: Periosteal spindle-celled, periosteal round-celled, periosteal osteoid, central round-celled, central spindle-celled, and central giant-celled. Like similar neoplasms of the soft parts, they are met with at all ages, but are most frequent from the fifteenth to the thirty-fifth year, the average age at which they manifest themselves being the twenty-seventh year.

As I am informed that the patient is under the influence of the anæsthetic agent, I will merely add that the partly bony and partly periosteal capsule denotes that the tumor originated in the medullary canal of the radius. It is certainly not a small spindle or a small round-celled sarcoma, and the diagnosis rests between a large spindle-celled and a giant- or multinuclear-celled tumor. Although the radius is only exceptionally the seat of myeloid or giant-celled sarcoma, and although that disease is very uncommon after the fiftieth year, I am disposed to regard the tumor as being of that nature, from its slow growth, and the absence of pain and changes in the integuments, the subcutaneous veins, and the lymphatic glands, and from the excellent general condition of the patient.

After the application of Esmarch's bandage, I will amputate the arm at its middle by flaps made by cutting from without inward. Instead of amputation, I might excise the affected bone; but the existence of the soft bosses, and the encircling of the limb by the growth, denote that the neighboring tissues are probably implicated by extension of the disease, and that it is adherent to the periosteum of the ulna and the interosseous membrane. Hence, excision would be likely to be followed by recurrence. Besides, the operation would involve the opening of the wrist-joint, which would be liable to be followed by suppuration of the joint, thereby enhancing the dangers of operative interference, and necessitating secondary amputation, to save life.*

* The limb was removed in the way indicated, and three arteries were ligated. Sections of the tumor, made by Dr. MacConnell, disclosed that it was an exquisite example of giant-celled tumor.—*Reporter.*

Medical Societies.

BRITISH MEDICAL ASSOCIATION—SECTION OF OBSTETRIC MEDICINE.

(*Continued from page* 293).

The chair in this Section was taken by Dr. George H. Kidd, of Dublin. The first subject for discussion was

Intra-uterine Medication.

Dr. Lombe Atthill remarked that (excluding all cases in which tumors of the uterus or polypus existed, and those resulting from anæmia) it would be found that the symptoms indicating the necessity of intra-uterine medication were: 1. Derangement of the menstrual function, specially hemorrhagia and dysmenorrhœa; 2. Uterine catarrh; 3. Pain, specially that caused by pressing the point of the sound against the fundus; one or more of these being present. With respect to the method to be employed in carrying out intra-uterine medication, Dr. Atthill objected to intra-uterine injections, and found ointment inefficient. He employed the following agents only—the fluids being applied by means of a probe, around the extremity of which cotton was wrapped, and the solids through a tube or *porte caustique*; carbolic acid in solution; tincture of iodine; iodized phenol; nitric acid; solid nitrate of silver; zinc points; crayons of iodoform. Carbolic acid was the agent Dr. Atthill recommended for ordinary use, being at once safe and efficient. Iodized phenol he recommended in cases requiring more energetic treatment, but considered it inferior to nitric acid; this latter agent, he pointed out, should never be applied to the intra-uterine surface, unless through a cannula or tube. This was a point on which he strongly insisted; and further, that the patient should be confined to bed for a day, or even more, subsequently; and he expressed his conviction that if these precautions were adopted no unpleasant results need be feared.

Dr. Robert Battey, of Ga., introduced to the Association his use of iodized phenol, already familiar to the American profession.

Dr. E. J. Tilt, though not much in favor of

this method, admitted, however, that intra-uterine medication was wanted in the following cases: 1. Incoercible blood-loss, resisting all remedies and menacing life; 2. When life or reason is menaced by the intensity with which internal metritis reacts on the system, rather than by the amount of purulent discharge to which it gives rise; 3. When internal metritis causes an aggravated complication of dysmenorrhœa by menorrhagia independent of ovaritis, and menacing life or reason; 4. Membranous dysmenorrhœa; 5. In habitual abortion, independent of syphilis and ovaritis, and seemingly caused by some morbid state of the lining membrane of the body of the womb. When internal metritis led to dangerous flooding, and in cases of membranous dysmenorrhœa, Dr. Tilt recommended intra-uterine injections with undiluted tincture of iodine. He deprecated the injection of a solution of nitrate of silver in such cases, and in other cases of internal metritis requiring intra-uterine treatment, on account of the severe pelvic diseases and death which had succeeded. In such cases he preferred to place in the womb five or six grains of solid nitrate of silver; but, as he had seen this followed by severe peritonitis, and as he knew this to have caused death, he expressed himself ready to welcome a better plan of treatment.

Dr. Byford (Chicago) believed that intra-uterine medication could be adopted in a great many instances with safety. When he applied it, he looked a good deal to getting the patient into a proper condition; made her live quietly for some time beforehand; and kept her in bed for two or three days after the application, which measures he found to secure success invariably. He thought that the application should be delayed after menstruation. He should hesitate to make an application of nitric acid to the uterus in a case where the canal and mouth of that organ was very much diminished in size; and he did not believe that these were the class of cases to which it was applicable. This treatment should be succeeded by more constitutional means. He used glycerine and extract of belladonna.

Dr. T. M. Madden presented a paper on

Post-partum Hemorrhage.

Having dwelt on the constitutional conditions predisposing to flooding, and the preventive measures by which this might be warded off, even in those who had been habitually subject to this accident on former occasions, he considered the causes of flooding and the management of labor so as to prevent subsequent inertia or irregular contraction of the uterus. The ill effect, in this respect, of the premature application of the forceps before the full dilatation of the os uteri, and also the production of hemorrhage as the result of undue delay in the second stage, were next referred to. During labor, when there was any reason to anticipate flooding, the preventive measures recommended by the author were: the rupture of the membranes in the first stage; the use of stimulating enemata of a strong infusion of ergot, or the hypodermic injection of ergotine, in the second stage; and a firm, unremitting manual pressure over the fundus uteri, from the time the child's head escaped from the vulva until the completion of the third stage, which should never be hastened by traction on the cord, and the permanent contraction of the uterus was secured. In nineteen cases of flooding, the solution of perchloride of iron was resorted to; in eighteen of these the hemorrhage was thus arrested, and in one instance it failed. Dr. Madden, however considered that the ordinary mode of using this styptic, viz.: by a syringe passed up to the fundus uteri, was a very hazardous proceeding, and exposed the patient to great and needless twofold danger of death from embolism or peritonitis. He, therefore, recommended instead the direct application of the strong liquor ferri perchloridi to the bleeding vessels by a sponge soaked in this fluid, and carried up by the hand into the uterus, and retained there until a firm contraction was produced. Some cases were referred to in which hemorrhage that had resisted all other treatment was thus arrested; and Dr. Madden, therefore, regarded this as the most effectual method of treating flooding. At the same time, he admitted that it was not free from danger, or even to be adopted without grave necessity. Some of the other remedies employed in the treatment of post-partum hemorrhage, including the hypodermic use of ergotine, galvanism, and cold and hot injections, were referred to. The treatment of collapse from flooding by brandy, opium, stimulating enemata, hypodermic injection of sulphuric ether, and transfusion, were considered. Dr. Madden related a case in which a patient, apparently at the last extremity, was rescued from death by the subcutaneous injection of ether, which he regarded as being in many instances a substitute for transfusion. The latter operation was, he considered, destined to fill an important place in the future practice of midwifery. But, as yet, no method of transfusion has been suggested which met the requirements of what, to be useful, should be a generally feasible as well as an effectual operation.

Dr. Wm. Walter read the report of eleven cases of

Post-partum Hemorrhage Treated by Intra-uterine Injection of Hot Water.

The temperature of the water used ranged from 100° to 120° Fahr.; and the utmost care was taken that the tube (Hayes') reached well up to the fundus; and that there was afterward no impediment to the escape of the water from the uterus. The results in the eleven cases, particulars of which were given, led Dr. Walter to the conclusion that the hot water treatment offered some advantages, in being generally accessible and not disagreeable to the patient; but that, as a means of contracting the uterus, it was, in his experience, not to be relied on. Nevertheless, he hoped to continue the method; and he advised that the temperature of the water should be ascertained by the thermometer in every case. The recent researches of Dr. Max Runge tended to show that, if success was to follow the hot water treatment of post-partum hemorrhage, the temperature of the water must not be so high as it was in Dr. Walter's cases. In all the cases but one the injection was followed by relaxation and dilatation of the entire

uterus; if contraction occurred, it was but temporary: but, when the temperature of the water did not exceed 104° Fahr., the uterus contracted without being afterward paralyzed. No appreciable effect was produced on the pulse and general condition of the system. After the failure of the injection, the application of the induced current was successful in several of the cases.

Dr. B. Battey gave an account of

15 Cases of Battey's Operation.

The mortality had been 13⅓ per cent. Regarding the results obtained at the end of six months, separating the recovered cases into three classes, there were three cases (*a*) of removal of but one ovary, three cases (*b*) of imperfect removal of both ovaries, and seven cases (*c*) of complete removal of both ovaries, which compared as follows: Morbid conditions wholly disappeared in class *a*, 1; in class *c*, 6; partly disappeared in class *a*, 1; in *b*, 1; not benefited, class *a*, 1; class *b*, 2; too recent to determine, class *c*, 1. *Present condition.*—Perfect health, class *a*, 1; class *c*, 4; comfortable health, class *a*, 1; class *b*, 1; class *c*, 2; not benefited, class *a*, 1; class *b*, 2; too recent to determine, class *c*, 1.

Dr. Graily Hewitt spoke of

Vomiting in Pregnancy.

He believed that the vomiting of pregnancy was one of the reflex disturbances produced by resistance to the normal expansion of the tissues at and immediately surrounding the internal uterine orifice. The success that had attended dilatation by Dr. Copeman's method was to be explained in two ways: (1) by the change of the flexed condition of the uterus—which the author had pointed out to be a usual cause of the sickness—to a condition of comparative straightness; (2) by the relief of the compression and condensation of the tissues by the artificial dilatation. Relief from vomiting during pregnancy might be obtained (1) by elevating the body of the uterus, and thereby taking off the pressure at the internal os; or (2) by dilatation of the cervix after the method of Dr. Copeman. His own opinion, based on observation, was that the postural treatment was generally sufficient.

The President said he had learned at the beginning of his career, from Dr. Henry Bennet's book, that inflammation of the cervix uteri was a frequent cause of the excessive vomiting in early pregnancy; and he had since made it a rule to examine the uterus in such cases, and frequently found the condition described by Dr. Bennet; and, on touching the inflamed surface freely with the solid nitrate of silver, the vomiting generally ceased.

Dr. H. Byford, of Chicago, read a paper on

Treatment of Fibroid Uterine Tumors by Ergot.

His positions were—1. When properly administered, ergot frequently very greatly ameliorates some of the troublesome and even dangerous conditions of fibroid tumors of the uterus, *e.g.*, hemorrhage and copious leucorrhœa. 2. It often arrests their growth, and checks hemorrhage. 3. In many instances it causes the absorption of the tumor, occasionally without giving the patient any inconvenience; while, at other times, the removal of the tumor by absorption is attended by painful contractions and tenderness of the uterus. 4. By inducing uterine contraction, it causes the expulsion of the polypoid variety of the submucous tumor. 5. In the same way, it causes the disruption and discharge of the intramural tumor. He said that, in administering ergot in cases of fibrous tumor, the action of the drug would depend on the degree of development of the fibres of the uterus, and on the position of the tumor with reference to the serous or the mucous surfaces; the nearer the mucous surface the better the effect. A good result might be expected under the following conditions: smoothness of contour of the tumor, denoting uniform development; hemorrhage; a lengthened uterine cavity; and elasticity of the tumor. He would expect large fibro-cystic tumors to resist the action of ergot; and a good result was not to be expected in cases of uneven nodulated tumor, absence of hemorrhage, shortness of the uterine cavity, and hardness of tumor. It was not essential to give ergot hypodermically, though this was a very efficacious method; it might be given by the mouth, in suppositories, etc. If the object were to cause painless absorption of the tumor, the dose should be moderate, and not too frequently repeated; if it were desired to have the tumor expelled, full and increasing doses should be given often, and continued till the object was attained. The preparation which he used was Squibb's fluid extract of ergot. He said, in conclusion, that he disclaimed any expectation that ergot would supplant all other modes of treatment.

The President stated that he had tried the ergot but had no good results from it in this class of cases.

Dr. Hodgen, of St. Louis, presented a paper and specimen of fibro-myoma of the placenta.

AMERICAN GYNÆCOLOGICAL SOCIETY.

This Society convened for its fourth annual meeting, at the hall of the Johns Hopkins University, Baltimore, Md., September 17th, 1879. The President, Dr. T. Gaillard Thomas, in the chair.

FIRST DAY.

There was a full attendance of members and also of many local physicians. Addresses of welcome were read by Dr. W. T. Howard and Professor D. Gilman.

Papers were read, by Dr. J. P. White, on intra-uterine medication, and on iodized phenol for this purpose, by Dr. Robert Battey, of Georgia. In the discussion which followed, Dr. J. Marion Sims said he believed there was a much shorter method of treatment, namely, that afforded by the use of the curette. He had recently seen several cases of cervical catarrh which had been cured by first dilating the cervix and then scraping away the fungoid granulations, and subsequently cauterizing the denuded surface with the actual cautery. This method of treatment was also favored by Dr. Taylor, who, however, used instead of the actual cautery an iron

only slightly heated and applied rapidly over the seat of the disease.

Dr. Howard thought that the great difficulty in treating cases of this kind was in not sufficiently making out a correct diagnosis of just what the trouble within the uterus is before beginning the treatment. It was especially necessary first to get rid of all uterine flexions. The use of strong acids or nitrate of silver was altogether too dangerous.

Dr. Barker had used cones of iodoform after first dilating the cervix with sea-tangle.

Dr. Byrne believed that a perfectly healthy uterus would not tolerate any liquid within its cavity. Nitrate of silver in solution, or chloride of zinc he thought, were most dangerous agents, and should never under any circumstances be applied within the uterus. The further the uterus we are dealing with has departed from a healthy condition, the greater will be its toleration of internal medication.

Dr. Goodell believed that great care should be used in the introduction of sponge tents. He always preferred to accomplish what dilatation was needed with one introduction of the tents, and thought that the best results were attained by using a small sponge tent surrounded by one or more laminaria tents. He had used the phenol recommended by Dr. Battey, but in combination with hydrate of chloral. He also thought that the pain often experienced by women as the probe or sound passes the internal os is occasioned by the presence at that point of a fissure or tender cicatrix. Such cases are often cured by dilatation at that point.

Dr. Thomas was, as a rule, entirely opposed to intra-uterine medication. He considered that such applications made within the os internum were very dangerous, as well as generally useless. There is usually some cause for the catarrhal condition, and it is not infrequently due to a flexion or misplacement. In cases where fungosities exist, the curette is of great value. In many cases a lacerated cervix is the cause of the difficulty, while in others there are constitutional causes to be removed. In cases of true idiopathic catarrh, which are always very rare, intra-uterine medication is of value.

Papers on the treatment of puerperal septicæmia by intra-uterine injections, by Dr. Jenks; and on idiopathic septicæmia, by Dr. Chadwick, were read. The latter favored the use of permanganate of potash for this purpose.

In the discussion Dr. Engelman mentioned accidents from the use of carbolic acid in this manner. Dr. Barker had witnessed five deaths from these medications. Dr. Goodell favored the use of permanganate of potash, and recommended the delivery of the placenta with the patient lying on her back, as this aided in preventing air from entering the uterine sinuses.

SECOND DAY.

Dr. Busey read a paper on the "Pathology of the Cicatrices of Pregnancy." He referred to the value of these scar-like streaks and spots as a sign of existing or previous pregnancies. Then followed a discussion of the anatomy of the striæ and the nature of the lesion giving rise to these appearances. The investigations of Kustner, accompanied with photographic illustrations of sections of striæ prepared by him, were presented, together with original microscopical examinations of the normal integument and of the striæ. From comparison of these histological appearances, Dr. Busey reached the conclusion that the striæ are not caused by rupture of the Malpighian layer, as generally believed, nor by separation of the fibres of any of the layers of the skin. He then discussed the several methods of vesicle formations, and concluded that the striæ of pregnancy do not constitute any form or stage of vesiculation, but that the hydrophic condition not infrequently observed is to be ascribed to the transudation of fluid into the lymph spaces of the connective tissue. In conclusion, he maintained that the striæ of pregnancy are localized atrophies of all the constituent layers of the integument, with compression and partial obliteration of the lymph spaces.

Dr. Mundé read a paper on "Prolapse of the Ovary," at the conclusion of which Dr. Thomas, the President, delivered the Annual Address, on the "Relations of Gynæcology to Surgery."

In discussing Dr. Mundé's paper, Dr. Barker stated that constipation was a powerful agent, not only in causing this displacement, but also in keeping the organ displaced. He believed that very little good was to be obtained from the use of pessaries for effecting a replacement of the ovary.

Dr. Busey believed that the structural changes observed in these cases were the result, and not the cause, of the displacements.

Dr. Byrne exhibited a galvano-cautery for the performance of kolpo-cystotomy.

In a paper on the size of the uterine cavity in childbed, Dr. Sinclair stated that its average length in the third week is 3.02 inches, that in primiparæ averaging 2.94 inches, and in multiparæ 3.21 inches.

THIRD DAY.

The annual meeting for business was held in the morning. The following officers were elected to serve the ensuing year:—

President, Dr. J. Marion Sims, New York. Vice-Presidents, Dr. W. T. Howard, Baltimore; and Dr. Robert Battey, Georgia. Council, Dr. W. Goodell, of Philadelphia; Dr. E. W. Jenks, of Chicago; Dr. A. D. Sinclair, of Boston; and Dr. A. J. C. Skene, of Brooklyn. Secretary, Dr. J. R. Chadwick, of Boston. Treasurer, Dr. P. F. Mundé, of New York. The following were elected Fellows of the Society: Dr. John Scott, of San Francisco; Dr. Edward L. Duer, of Philadelphia; Dr. R. Stansbury Sutton, of Pittsburgh; and Dr. J. W. Underhill, of Cincinnati.

It was voted that the next meeting of the Society be held in Cincinnati, and the time was fixed for the first Wednesday in September, 1880.

The reading of papers began with a paper by Dr. I. E. Taylor, on the Early Application of the Forceps in the First Stage of Natural Labor. In it the writer strongly advocated the application of the forceps within the uterine cavity whenever there were symptoms of an approaching tedious labor.

Dr. Howard believed that great advantage

could be gained by the use of hot water vaginal injection, and that when the os uteri was dilated so as to admit of version being performed that operation was preferable to the introduction of the forceps.

Dr. Goodell read a paper based on clinical notes on the Hypertrophic Elongation of the Cervix Uteri, in which the writer favored, under certain circumstances, the amputation of the cervix with the actual cautery.

Papers were read, by Dr. Johnson, on Mismanaged Labors, and by Dr. Reeve, on Extra-uterine Pregnancy, and the Society adjourned.

Editorial Department.

Periscope.

Treatment of Croupous Pneumonia.

Dr. D. W. Prentiss gives his treatment as follows, in the New Orleans *Medical and Surgical Journal*:—

I have never used *cold* baths in this disease, but have prepared water at a temperature of 90° and reduced it ten degrees during the fifteen minutes occupied in administering it.

Not that I believe any risk would be run by making the bath cold, but experience goes to show that quite as great reduction of temperature is obtained from the above graduated bath, with certainly greater comfort to the patient, and less violence to the prejudices of friends.

If we consider for a moment the modus operandi by which the bath is an effective measure in reducing temperature, I think we will be disposed to admit that the warm bath should have the preference.

The *skin* is the organ by which the balance of temperature is preserved between the internal structures and external surface, and through the agency of the blood. A very great extent of surface in the capillary vessels of the skin is exposed to the cooling influence of the external air with every pulsation of the heart, and the extent to which the surplus heat of body combustion is got rid of is exactly in proportion to the amount of blood so exposed to the air in the skin, and the condition of the skin at the time.

The application of cold contracts the capillaries of the skin and drives the blood away from the surface toward the internal organs.

This is the effect of a cold bath, and although the reduction of temperature in the blood still remaining in the skin is greater than from a tepid bath, still the aggregate effect will be less.

The warm bath relaxes the skin and invites blood to the surface, while the difference in temperature between water at 90° and fever heat (104° or upward) is quite sufficient to give a decided clinical result.

In addition, the absence of shock and greater feeling of comfort to the patient is an advantage of the warm bath not to be overlooked.

In some of these cases, where the convenience of a bath tub was not to be had, a common washing tub was used, the patient sitting in it, covered over the shoulders with a blanket, and this was found to be an efficient substitute.

Whenever the patient became prostrated from the fever, or oppressed by the dyspnœa, the baths were discontinued and quinine relied on as an antipyretic. In children, if the baths were the occasion of struggling and screaming, they were not insisted on, the wet towel and quinine being resorted to.

The dose of quinine given to adults was from grs. xv to grs. xx, and was found to be sufficient.

The reduction of temperature varied in different cases, from 1.5° to 4.7°, and lasted about fourteen hours from the time of administration. A dose given at midday would show decided effect in three hours, reach its maximum at nine o'clock P.M., and the temperature would begin to rise about two o'clock A.M.

In the severer cases the temperature would be again the following morning as high as before its administration. In the milder cases the fever did not appear to rise as high any more after the first dose of quinine.

In some of the cases it produced a decided hypnotic effect, every full dose being followed by quiet sleep.

Dr. S. C. Busey said he had frequently noticed the same effect. He had had his attention first called to it by Dr. Jas. C. Hall, of this city, a most acute observer, who had been in the habit for years of giving quinine at bedtime, with the double purpose of promoting sleep and at the same time avoiding the annoyance of noises in the head occasioned by this agent.

Stimulants were administered as required. Carbonate of ammonia as a special cardiac stimulant where the respiration was embarrassed.

Milk and beef tea were relied on for nourishment.

The Combination of Iron and Chloride of Ammonium in Heart Disease.

In the *Practitioner*, Prof. T. Grainger Stuart cites a case of cardiac disease, and adds these general remarks:—

This case afforded an example of a condition by no means uncommon, but of which I have been unable to find a satisfactory description in books. The first glance at the patient leads one to notice the pallor, the very anxious expression, the restlessness, the pale lividity of the lips, the throbbing of the carotids, and perhaps of the temporal arteries: while the patient complains of giddiness, perhaps of headache, certainly of breathlessness, and of a debility that amounts at times to faintness. He is somewhat relieved by food, and unless there is some dropsical effusion to prevent it, he is easier in the recumbent posi-

tion. But he obtains very little sleep. The explanation of his various symptoms is readily found. The pallor and the head symptoms are due in part to anæmic deterioration of the blood and partly to imperfect filling of the arteries supplying the face and brain. The throbbing is due to the ill-filled condition of the arteries, contrasting with their sudden temporary filling during the ventricular systole; while the breathlessness and the lividity are connected with the dilatation and the partial failure of the heart's action. Sometimes the distress is aggravated by the existence of dropsical effusion, and it seems to be specially severe when the pericardium is its seat. Such cases sometimes prove rapidly fatal by sudden syncope, and sometimes death follows upon a long agony, characterized mainly by symptoms of cerebral anæmia. These cases do not seem ever to recover spontaneously.

Treatment by the administration of cardiac tonics, and especially of iron, leads in many cases to decided improvement. The form which I find best is the tincture of perchloride, but it must be given in large quantity. I have gradually been led to give it in larger doses; sometimes even to the amount of twenty minims every two hours, more frequently every four hours, continuing its use for days together. In many cases the patients speedily experience relief, and before long there is manifest improvement. As in the patient whose history I have given, they are enabled after a time to leave the hospital and return to work.

But there is great difficulty in carrying out this plan of treatment, from the gastric and hepatic derangement which so frequently follows upon the use of iron. During the past two years I have sought to meet this difficulty by combining chloride of ammonium with the iron, ½ gr. to each minim of the tincture. During that time I have repeatedly been thus enabled to administer iron in large doses in combination with chloride, to patients who otherwise could scarcely have used iron. It will be observed that in the case now recorded the iron speedily led to dyspeptic symptoms, so that it was impossible to persevere with its use. But the addition of the chloride both relieved the existing dyspepsia and enabled us to continue to administer the iron in large doses, and for a considerable time. So far as I can judge, iron is the only remedy which could have saved the life of the patient at the time, and but for this effect of the chloride of ammonium, I do not know how I could have administered iron so freely as to suffice.

The Sedative Treatment in the Excitement of the Insane.

Dr. J. N. Campbell says, in the *Lancet*, as a sedative, given continuously, I have principally used bromide of potassium in combination with tincture of cannabis indica, or with tincture of hyoscyamus, compound tincture of valerian, and occasionally tincture of opium. Alone, bromide of potassium is valueless in the treatment of acute excitement; its immediate action is too weak; in time it produces bromidism; but I think it acts like a drag in combination, keeping up a sedative effect. In the 101 cases in which I gave a sleep producer, I had a note made of when the patient became quiet and slept, as far as possible in each case, and recorded it. In these cases I almost entirely used chloral, and am satisfied with its certainty of action and harmlessness when given for short periods. I gave it in doses of from twenty to thirty-five grains (seldom exceeding the latter) in a glass of sherry, administering the medicine after the patient had been in bed an hour without sleeping. I simply gave it to cause sleep. If a patient falls asleep, he will in nearly every case go on sleeping. I did not wish it to produce a long-lasting, drugged sleep. I am quite sure that when first introduced chloral was given in too large doses, too frequently and for too long periods. I now never use it for any great length of time. Much care should be taken to ensure quiet surroundings at night for recent acute cases. Frequently new excitable cases cannot sleep in an associated dormitory, but if put in a room by themselves they may. With the chronic patients I find I gave a sleep producer, in all, to thirty-three, for different and repeated periods, during the term of years I am referring to, and in many instances the medicine was given more for the sake of others who might be disturbed than for the sake of the recipient. I find that I need not now give so many draughts to cause sleep; the chronic patients sleep better. I used sedatives continuously during the day in the case of twenty-six chronic patients during these five years, to some of them for several periods of each year. In many cases I missed an excited attack and observed and recorded the course of the excitement as to its duration and intensity.

For several years I have been attempting to arrive at some conclusion as to the value of sedative treatment; and as to its real effects, if any, other than the merely quieting for the short time its action lasted after each dose, I still find difficulty in the matter. In recent cases laboring under acute excitement, it is impossible to predicate with anything like certainty whether the attack will be of long or short duration; there is nothing that I have noticed in any case to enable one to do so, though the age of the patient and the cause and variety of insanity may allow one at times to form a tolerable prognosis. I reported in 1875 three cases of short attacks of insanity, in which the excitement was very intense, but short-lived; and since then I have seen several similar cases, but nothing that I could notice in such or other cases of excitement would enable me to form a reliable prognosis as to the duration of the attack of excitement. This is what makes it so difficult to estimate with accuracy the value of medicinal or other treatment in excitement. In my practice during the last five years, I have noticed cases where periodic excitement came on usually at tolerably regular intervals, and ran a given course as to duration and intensity, at times vary much. In several cases that I especially observed, when treated during an attack, both with and without sedatives, I noticed that, when treated by continued sedatives, they remained longer in a stupid or mentally clouded state after the excitement passed off than when sedatives were not given.

Treatment of Diphtheria.

The following is from an article by Dr. C. D. Kingsford, in the *Lancet*:—

Since 1858 very many cases of diphtheria of varying type, some of a most malignant form, have occurred in my practice, and by adhering to the plan of treatment advocated the results have been most favorable. For several years I have discontinued to apply nitrate of silver and other topical remedies, and only made use of a weak gargle of Condy's fluid; but within the last twelve months I have painted the membranous deposits with lactic acid, one part in three of water, and in severe cases an efficient nurse has been instructed to do this every four hours. Quite lately, too, at the suggestion of Mr. D. de Berdt Hovell, I have brushed the throat twice a day with perchloride of iron and glycerine, in equal proportion, which acts by corroding, as it were, the membrane, causing it to pucker, and to be thrown off apparently earlier than would otherwise happen, also—no small matter—by entirely removing all fetor. But as the chief object of this communication is to put prominently forward the internal treatment, it may not be out of place to detail the plan I usually adopt. For an adult I order tincture of the perchloride of iron, forty to sixty minims, chlorate of potash ten grains, glycerine one drachm, water one ounce, to be given every two or three hours during the day and night; and as the case progresses toward recovery I prefer to increase the interval rather than to diminish the dose. This treatment should be strictly carried out from the moment the disease is recognized, so necessary is it to counteract the poison circulating in the system. An aperient, if indicated, may be given early, but not an emetic—at least I have never seen any benefit effected by one. In fatal cases I have invariably had to regret that larger doses of iron had not been given from the commencement of the attack. Nourishment, such as milk, beef tea, eggs, etc., must be given every two or three hours throughout the day and night, and so great is the tendency to exhaustion that there should never be any hesitation in having the patient aroused for food and medicine. With regard to stimulants, from the very circumstance of their being almost always required, some care should be shown in the choice and mode of administration; indeed, from want of judgment in this respect, I have seen very baneful results. I find, as a rule, an ounce and a half of port wine given every three or four hours better borne and more sustaining than frequent doses of brandy, and far less liable to excite the sensorium; very rarely, if ever, is it wise to have recourse to more than one form of stimulant. The indiscriminate use of various kinds of wine and different sorts of spirits is to be especially deprecated. A constant supply of steam generated in the room, but not too near the bed, is a desideratum in the management of all cases of diphtheria, and becomes absolutely necessary whenever the air passages are involved.

When the larynx is affected there is grave cause for anxiety; still, even here I would advise steady perseverance in the iron treatment, for from long experience I have learned that as when pneumonia occurs in the course of fever we dare not relax in our general treatment of the fever, so also in these laryngeal attacks we must remember that we are engaged in combating another stage only of the same disease (diphtheria), but which from its situation is now threatening to close the door against the ingress and egress of the very breath of life. In these cases I have frequently been induced to try special treatment, but have always had to return to the iron and potash mixture, and to regret the time and ground lost by the deviation.

Carbolic Acid a Remedy Against Bee Stings

Dr. Klamann publishes, in the *Allgemeine Medicin. Central Zeitung*, a case of bee sting, followed by acute symptoms of poisoning, which was relieved within a very short time by a subcutaneous injection of carbolic acid. The patient, a robust, strongly built young woman, was stung in the lower lip by a bee. Soon afterward she vomited; her face became flushed; the right half of the face began to swell, and the swelling soon spread over the whole face. The woman fainted, and was laid on her bed. When Dr. Klamann saw her, soon afterward, he found her unconscious; the face was dark red, and much swollen; the sclerotics were injected, the lips cyanotic, the lids œdematous, the fingers and toes pale and cold. The patient did not answer when spoken to; the pulse was 72, hardly perceptible; respirations 24. Nothing abnormal could be detected in the heart, but the impulse was weak. The extremities were immovable. Cold compresses were immediately applied to her head, and five milligrams of carbolic acid in solution were injected under the skin, near the spot where she had been stung. At the same time sal volatile was held to her nose. In about a quarter of an hour the swelling of the lips and eyelids began to abate visibly, consciousness returned gradually, and the mouth could be opened. The tongue was somewhat swollen, but the patient could swallow without much difficulty. In the course of three-quarters of an hour the patient had three attacks of convulsive trembling of the whole body, together with violent twitchings of the muscles of the face. During each of these attacks the patient was very restless; her face became flushed, and she threw her head about. After each attack her face became suddenly pale, the skin of her whole body grew cool, and the pulse could hardly be felt. Gradually, however, the symptoms of poisoning disappeared, the patient could open her mouth and swallow a few drops of spirit of sal volatile in water. She passed a good night, and the next day went about her work as usual. The lower lip remained slightly swollen during the next few days. A fortnight before the accident she had been stung by a bee in the left forearm; after which the whole limb became swollen, and urticaria broke out over the whole body. The arm was still swollen when she was stung in the lip; and the injection of carbolic acid appeared to exercise a favorable influence on the arm, which, on the next day, had recovered its natural size.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——The fourth of the American Health Primers is entitled, "Eyesight, and how to Care for it," by Dr. George C. Harlan. It describes in clear language the anatomy of the eye, the physiology of vision, the use of the ophthalmoscope, the more common injuries, diseases and defects of the eye; the choice and employment of spectacles, and concludes with a series of practical suggestions for the cure of the eyes, and a discussion of the effects of school life upon the sight. Published by Lindsay & Blakiston. Price, cloth, 50 cents.

——In a little work of fifty pages, entitled "First Step in Chemical Principles," Dr. Henry Leffmann endeavors quite successfully to make clear to beginners those points in theory, notation and nomenclature which give them the most trouble to understand. His language is clear; the illustrations ample, and undoubtedly the study of this little treatise will smooth to the student the very rugged paths of modern chemical theory and nomenclature. Published by Edward Stern & Co., Philadelphia.

——The connection of the hepatic functions with uterine hyperæmias, fluxions, congestions and inflammations, is the subject of a reprint by Dr. L. F. Warner, of Boston. The main object is to prove that the successful treatment of uterine hyperæmias, fluxions, congestions and inflammations must often depend as much upon measures that are termed constitutional as upon those that are strictly local, and that sometimes without them it is impossible.

BOOK NOTICES.

Student's Pocket Medical Lexicon: Giving the Correct pronunciations and definitions of all words and terms in general use in medicine and the collateral sciences, the pronunciation being plainly represented in the American phonetic alphabet, with an appendix containing a list of poisons and their antidotes, abbreviations used in prescriptions and a metric scale of doses. By Chas. Longley. Phila., Lindsay & Blakiston, 1879. Cloth. $1.00.

This small book with the long title is one of more promise than performance. It bears evidence on its face that it is a compilation by a person quite ignorant of medical science. Why one not even a member of the profession should undertake to write a medical dictionary, is hard to imagine. It abounds with names of useless drugs and obsolete terms, and omits most of these recently brought into general use. Thus we have looked in vain for athetosis, atelectasis, autophony, anode, cathode, hospitalism, neurasthenia, plessimetry, seborrhea and a number of other words common in medical language. Its definitions are often absurdly erroneous; thus the retina is defined to be "the expansion of the optic nerve which forms the inner coat of the eye;" angina pectoris is "a spasm of the nerves of the chest;" angular artery is "the termination of veins near the inner angle of the eye:" schirrhus is "a hard tumor affecting the glands, often ending in cancer;" cancer is "schirrous tumor terminating in a malignant ulcer;" autopsy, "personal inspection." These definitions are evidently by one ignorant of the rudiments of medicine, who has borrowed without judgment, from obsolete authorities. We recommend all students to avoid the purchase of the book.

A Guide to Surgical Diagnosis. By Christopher Heath, F.R.C.S., etc. Philadelphia, Lindsay & Blakiston, 1879. Cloth, 8vo, pp. 214. Price $1.50.

This essay on surgical diagnosis groups surgical affections anatomically, and under this anatomical division aims to group the symptoms of each disease in the order in which they would strike a close observer. Thus, in reference to the head, we first have tumors and wounds of the scalp, fractures of the skull, concussion and compression of the brain, affections of the face, the eye, the ear, the nose, the mouth, and the jaw. Of these, under, for instance the nose, we have the symptoms detailed of inflammation, erysipelas, acne, lipoma, ulceration, chronic discharge, ozæna, necrosis, suppuration of the antrum, polypus, vascular growth and obstruction, the whole compressed into three pages. Necessarily this necessitates an amount of condensation for which completeness must be frequently sacrificed. The author seeks to make amends by giving only the most prominent diagnostic features; and as he is a skillful surgeon and finished writer, he succeeds remarkably well within the self-imposed limits he has chosen. The whole field of surgery is included, differential points being prominently brought into light, often by means of the tabular method. It is, indeed, the most satisfactory book of the class which has come to our notice.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Half-Yearly Compendium of Med. Science,	**2.50**
Reporter and Compendium, - - -	**7.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**8.25**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

WHAT PROGRESS THE METRIC SYSTEM IS MAKING AMONG US.

Last week we inquired of the three most prominent drug stores on the most fashionable street in this city, what proportion of their current prescriptions were written in the metric system. One answered about one per cent.; the second, very few except those received from abroad; the third, that they seldom received a prescription in this system, except from foreign physicians. These three stores probably do as large a prescription business as any three in the city; and they are located where they would first feel the effect of any such novelty.

The conclusion from this is that the introduction of the metric system, so far as Philadelphia is concerned, is an absolute failure.

There are many reasons for this, and good ones. When closely examined, there is by no means that simplicity about the metric system, nor is there that fixity about it, which its admirers have claimed. Its unit is notoriously based on a mathematical blunder, the meter not being the ten-millionth part of a quadrant of the meridian of Paris, as was supposed by those who first adopted it. It is wrong one meter in every five hundred and fifty-five thousand. Practically it is found very inconvenient to convert *accurately* apothecaries' into metric weights and measures. The *American Medical Biweekly* gives this example:—

"Suppose one desirous of prescribing twenty pills of arsenious acid, one-thirtieth of a grain each, the following would be the procedure: One grain is equal to sixty-five thousandths of a gram; a thirtieth of a grain is equal to one-thirtieth of sixty-five thousandths of a gram; this calculated is twenty-five ten-thousandths of a gram, and twenty times twenty-five ten-thousandths is five-hundredths of a gram, the amount the prescription would call for. This is a simple illustration, but it is enough to show that it is not as ready a method as is claimed for it; after the calculations are made the mere writing it is greatly simplified, but this is simple enough as it is."

In spite of care exercised in writing prescriptions, the metric system certainly offers greater facilities for errors in putting them up. A leading and skillful pharmacist in this city urged, in a conversation with us, that this alone is a sufficient objection to its introduction. Already, dangerous mistakes have been reported, and even fatal ones.

Another very great annoyance is that of prescribing fluids of all kinds by weight only; the volumes or cubic quantities are varying and uncertain. This is well put by Dr. J. F. BALDWIN, in a paper he read before the last meeting of the Ohio State Medical Society. Describing his experience in the use of the system, he says:—

"The principal trouble I have had has been in the feeling of uncertainty, when prescribing liquids, as to what would be the bulk of the resulting mixture. The familiar '*q.s. ad* —' of the old method sufficed to make the mixture equal a certain bulk; but the new system, at least as used in France and Germany, has no such convenient device. Not only does the difference in specific gravity lead to inaccuracy, but the various solids that are added also affect the bulk to a greater or less degree; so that it is impossible to predict, with anything like the degree of accuracy desired, the amount of medicine the patient will get."

Further, there has been no uniformity in the system itself as it has been presented to the American public. The Boston Metric Bureau advocates the Continental system, in which liquids are invariably prescribed by *weight*; the

Chicago Metric Club recommends the use of cubic centimeters—in other words, *volumes* for liquids; the United States Marine Hospital Service allows either to be used, believing that the difference of eight per cent. is "insignificant." But this is a great concession, and hardly to be admitted. Moreover, as the specific gravity of syrup is 1.317, should the prescriber assume that thirty grams of syrup equal an ounce, which would be true as regards water, and were he to use it as a vehicle, he would unwittingly increase the dose of his active drug one-fourth, which might entail disastrous results.

Various suggestions have been made to overcome these difficulties. By one of them it is stated in its favor that the approximate equivalents of grains and grams may be secured by means which might almost be styled mechanical. Let the physician prescribe his liquids, powders or pills, in a quantity equal to sixteen doses. Then every *gram* or *cubic centimeter* of active ingredient will be represented in *each dose* by a single *grain* or a single *minim*. But this is often inconvenient to do.

It has also been demanded in some quarters, whether we should humor the foreigners by adopting their plan of prescribing. Thus the Michigan *Medical News* says, editorially—

"We know of no reason why we should dance when our German and French brethren pipe, and especially when the music they give us is in such wretched time.

"America and England, together with English-speaking people the world over, are very slow to adopt the 'metric,' and we doubt whether it ever will become general among these people. If we were dependent on the French and Germans for all, or even a great part, of our scientific knowledge, we might feel it necessary to cater to their metric whim, but inasmuch as the great English-speaking people lead the world in science as applied to the useful arts, and to medicine and surgery in particular, there is nothing improper in their insisting that their European brethren shall come back to the old-time system from which they departed."

It is obvious, from the quotations and facts we have here gathered together, that the American profession does not intend to adopt the metric system at present, and that it declines doing so, not out of a blind conservatism nor a national pride, but because the system has serious drawbacks which have not yet been removed. Pharmacists, also, are, so far as we can learn, generally opposed to it; and while it is well for all physicians to be able to understand the metric method, both to read it and to write it, it were premature at this present time to adopt it in text books and treatises, or even in periodical literature. This may be considered as a general reply to the question we have been several times asked, why the Medical and Surgical Reporter does not adopt it exclusively.

Notes and Comments.

Therapeutical Notes.

METALLIC MERCURY IN SYPHILIS.

In the *Archiv. für Klin. Med.*, Dr. Furbringer recommends the hypodermic use of metallic quicksilver in syphilis. His formula is—

℞.	Hydrarg. depur.,	2.0
	Mucilag. acac.,	10.0

Rub well together, and gradually add—

℞.	Glycerin. puriss.,	10.0

This makes a permanent emulsion, not readily oxydizable. The absorption of mercury in this form is very gradual and efficient. About half a syringeful (= 0.050 metallic mercury) is an average dose.

A CHEAP ANTISEPTIC.

A new and cheap antiseptic is made by dissolving in water equal parts of chloride of potassium, nitrate of sodium, and boracic acid, filtering and evaporating to dryness. It is easily soluble in water, and is deliquescent. It passes under the unscientific name of double borate of potassium and sodium, and its action as an antiseptic is said to be prompt, and to continue undiminished for a long time. It is a good application, in solution, to ulcers, foul wounds, etc.

SEA WATER GARGLE IN CHRONIC CATARRH.

Professor Mosler, of Greifswald, says, in the *Berlin. Klinische Wochenschrift*, June 2d, 1879, that he has for some years most successfully treated patients with chronic catarrh of the throat by gargling with sea water. Special rooms for gargling have been erected on the seashore in some watering places, according to his directions. It is, however, essential that the patients should be given special directions how to gargle. As the affection is generally located in the naso-pharyngeal space, it is necessary that part of the water should come in contact with the nasal cavity. In order to attain this, the garg-

ling movements must be combined with movements of deglutition. A marked improvement in the state of the patient follows as soon as the latter has acquired this particular art of gargling.

BROMOHYDRIC ACID IN ULCER OF THE STOMACH.

A writer in the *Lancet* says he has found this acid useful in the treatment of chronic ulcer and other painful diseases of the stomach. It arrests the obstinate vomiting attendant on these diseases when all other means fail, thus enabling the stomach to retain food and medicines. By thus resting the stomach, bromohydric acid favors the administration of other remedies, and must expedite the cure when the case admits of it. He gives twenty minims to half a drachm in an ounce of water, every two hours at first, gradually reducing it to three or four times a day.

The Management of Opium and Morphia Poisoning.

Readers will remember that Dr. Sholl recited, some time ago, in the REPORTER, a case of morphia poisoning successfully treated by veratrum viride. In the *Lancet and Clinic*, Dr. J. S. Haldemann adds to this a similar instance from the *Cosmos*, and concludes a general review of the physiological antidotes of morphia with these words:—

"I have great faith in the veratrum viride as an antidote to morphia poisoning. It is undoubtedly a powerful alterative and nervine, and has indisputable arterial sedative virtue. Therefore, should I be required to treat a case where the deep, hypnotic effects of morphia had to be counteracted, I should be inclined, most certainly, to give this article the first, and a fair trial. If it then should fail me, my next resort would be strychnia; and if disappointed in it, then belladonna would 'come in' for a trial, together with such topical applications and remedies as would naturally and rationally suggest themselves."

The Sclerostoma or Anchilostoma Duodenale.

On page 40 of this volume a case of this parasite in this country is noticed, and its frequency in Egypt mentioned. Since then we see in an exchange that Dr. P. Sonsino, an Italian physician, found that in nine neuroscopies made in Cairo, seven of the cadavers contained this parasite. In a communication made last year to the *Società Medico-fisica*, of Florence, he stated that these worms are found firmly attached to the mucous membrane of the duodenum and jejunum; after eroding this membrane they suck out the blood, and thus abstract it from the individual. When there are many present a considerable amount of blood is lost, and hence there is more or less intense anæmia. In a woman dying of anæmia perniciosa progressiva at the hospital in Florence, the intestines were found to be very thin, pallid, and almost transparent. Hundreds of the parasites were found in the jejunum, and a number in the ileum. They were dead, and attached to the mucous membrane, which presented corresponding grayish ecchymoses. No other lesions were found sufficient to account for the profound anæmia.

Report of the Philadelphia Board of Health.

This valuable document makes a volume of nearly four hundred pages. The portion devoted to the statistics of births, deaths and marriages occupies nearly a third of this. They relate to the year 1876, and have been most carefully compiled and arranged by Dr. Wm. H. Ford, now President of the Board, and Dr. R. A. Cleemann. Many curious results are reached: as that in this city the excess of male over female births is considerably above the average; that the birth rate among the colored population is deficient and their number almost stationary; that the autumn and winter months are invariably the most prolific, and the spring months least so; that after the crisis of 1873, there was and continues a marked decrease in the number of marriages; that nearly one-half the deaths occur before the completion of the tenth year, and nearly one-quarter (24.09) before the completion of the first year; and many more. The relation of sewer gas to typhoid fever is fully discussed, and the connection affirmed to be close. A large number of charts and diagrams are inserted, and a very careful meteorological record.

The report of Dr. W. M. Welch, physician in charge of the Municipal Hospital, is particularly full on the subject of smallpox and its complications.

Varieties of Psoriasis Palmaris.

Dr. Wm. Cottle writes to the *British Medical Journal*—

I am in the habit of recognizing five distinct diseases that are wont to occur on the palm or sole without other parts being necessarily simultaneously involved, and which may present a not very dissimilar appearance, namely, eczema, psoriasis, syphilis, lichen ruber, and erythematous lupus. I have frequently met with psoriasis in this situation as part of the general

non-syphilitic disease, often in gouty subjects, and with no coexisting eczema. There is also a form of palmar psoriasis to which the late Mr. Nayler first called my attention, and which, for the sake of distinction, he was in the habit of designating "non-specific palmar psoriasis." In these cases the skin of the whole palmar surface of the hand, fingers and thumb is red, thickened and hard, and the natural furrows of the skin occupied by small white scales, so that the whole surface is mapped out with fine white lines. No cracks nor fissures are present, and the part is always dry and harsh, and generally hot and irritable. The condition may exist with or without psoriasis in other situations, and nearly always occurs in women.

Commercial Impositions on the Profession.

In the September number of the Chicago *Pharmacist and Chemist* a striking example of the imposition practiced on the profession by some unscrupulous drug firms is mentioned. A circular issued by Merrill, Thorp & Lloyd, of Cincinnati, is quoted, advertising *alstonia constricta* as an ague cure, ingeniously intimating that its great value may soon make it quite scarce, and offering the powdered plant at $1.00 per ounce. The regular wholesale price in New York city, of this almost worthless drug, is 85 cents to $1.00 *per pound!*

It is a duty which we cheerfully perform to put our readers on their guard against all firms who endeavor to exploit the profession in this manner.

Mesmeric Anæsthesia.

An interesting illustration of this curious condition is reported to the New Orleans *Medical and Surgical Journal*, by Dr. E. L. Day, of Texas. It is as follows:—

"Willis Francis, colored man, about 25 years of age, had his great toe badly injured by having heavy iron rollers fall upon it. About ten days after the injury he consulted Dr. Legreud, who decided to amputate, and as an experiment, called upon Mr. James Armstrong, of this place, who claims the power of magnetization, to exercise this influence on his patient. The magnetizer commenced by passing his hands slowly and steadily in front of the patient's face for a period of five minutes, when he closed his eyes as though in sleep. The doctor then performed the operation, the patient remaining all the while in a state of complete anæsthesia. By simply snapping his fingers sharply in the patient's face the influence was removed."

Fracture of the Fœtal Skull from Uterine Contraction.

The following case given by the Vienna correspondent of the *Canada Medical Journal* is one of great interest, not only to the obstetrician but also to the medical jurist. It proves that uterine muscular action alone is sufficient to cause fracture of the head of the fœtus. A powerfully-built woman, aged thirty-seven, was admitted into C. Braun's wards, in her ninth pregnancy. The previous eight labors were all severe. During the course of the labor rupture of the uterus took place, and a dead child was removed from the peritoneal cavity by abdominal section. The mother lived twenty-four hours. On post-mortem the uterus was found to be greatly hypertrophied. A rent 15 ctm. in its long diameter (transverse) was found in the cervical region, through which intestines protruded. The antero-posterior diameter of the inlet was considerably narrowed. On examining the child's head, the parietal bones superiorly were found to be completely separated, and a fracture in the right one 4 ctm. in length. There was effusion of blood upon the meninges.

Physiological Effects of Brucine and Strychnine.

Dr. Lautenbach reports experiments with these agents, in the *Medical Times*. His conclusions are as follows:—

Brucine treated with acetic acid injected into a Rana temporaria, in the proportion of one part of the alkaloid to about fifteen hundred parts by weight of the frog, produces a non-excitability of the motor nerves, through a direct action on these structures.

Brucine treated with hydrochloric acid produces the same effect in the Rana temporaria; but in the Rana esculenta it, in much smaller doses, paralyzes the motor nerves without having previously induced tetanus.

Strychnine treated with acetic or hydrochloric acid produces in the Rana temporaria paralysis of the motor nerves in one-sixth the dose necessary for brucine to produce the same effect

Bright's Disease.

The eminent Professor Bamberger has contributed a very able study of this disease to the Pesth *Med. Presse*. He believes that it is very much more frequent than is generally supposed, and often is not recognized by the attending physician. He does not believe in the modern divisions into parenchymatous and interstitial nephritis, and thinks it better to adhere to the old view, that the disease is one and single, presenting itself, however, either in primary or

secondary form, acute or chronic, etiological or symptomatic. He finds in phthisis 16 per cent., in aortic disease 9, in pregnancy 6, in chronic skin disease 5.2, in general urinary disease 5.5 per cent. of patients have albuminuria. In alcoholism he found but 4.8 per cent., and expresses his doubts whether this plays such a role in causing Bright's disease as many have said.

Evidences that Dead Infants were Born Alive.

At the conclusion of a close study of this subject, Dr. S. W. Abbott states, in the Boston *Medical and Surgical Journal*, that the medical examiner may infer that a child has lived during and after its birth, from the following signs:

1. When the diaphragm reaches only to the fifth intercostal space.
2. When the lungs more or less completely fill the thorax.
3. When the ground color of the lungs is broken by insular marblings.
4. When, by careful experiment, the lungs are found to be capable of floating.
5. When a bloody froth exudes from the cut surfaces of the lung on slight pressure.
6. When the air cells are visible to the naked eye.

These proofs, complete as they are, may be strengthened by the cicatrization of the umbilicus, the scaling of the epidermis, the closure of the fœtal ducts, the size of the osseous nucleus of the inferior femoral epiphysis, the existence of milk, sugar, starch, or medicines in the stomach, determined by the appropriate chemical tests, and by the presence of fecal matter other than meconium in the lower intestines.

Another Discoverer of the Circulation of the Blood.
